Table of Contents

I. Spring Boot Documentation	1
1. About the documentation	. 2
2. Getting help	3
3. First steps	. 4
4. Working with Spring Boot	5
5. Learning about Spring Boot features	6
6. Moving to production	7
7. Advanced topics	. 8
II. Getting started	9
8. Introducing Spring Boot	10
9. System Requirements	11
9.1. Servlet containers	. 11
10. Installing Spring Boot	12
10.1. Installation instructions for the Java developer	12
Maven installation	12
Gradle installation	13
10.2. Installing the Spring Boot CLI	14
Manual installation	
Installation with SDKMAN!	
OSX Homebrew installation	
MacPorts installation	
Command-line completion	
Quick start Spring CLI example	
10.3. Upgrading from an earlier version of Spring Boot	
11. Developing your first Spring Boot application	
11.1. Creating the POM	
11.2. Adding classpath dependencies	
11.3. Writing the code	
The @RestController and @RequestMapping annotations	
The @EnableAutoConfiguration annotation	
The "main" method	
11.4. Running the example	
11.5. Creating an executable jar	
12. What to read next	
III. Using Spring Boot	
13. Build systems	
13.1. Dependency management	
13.2. Maven	
Inheriting the starter parent	
Using Spring Boot without the parent POM	
Changing the Java version	
Using the Spring Boot Maven plugin	
13.3. Gradle	
13.4. Ant	
13.5. Starter POMs	
14. Structuring your code	
14.1. Using the "default" package	32

14.2. Locating the main application class	. 32
15. Configuration classes	. 34
15.1. Importing additional configuration classes	. 34
15.2. Importing XML configuration	. 34
16. Auto-configuration	35
16.1. Gradually replacing auto-configuration	. 35
16.2. Disabling specific auto-configuration	. 35
17. Spring Beans and dependency injection	. 36
18. Using the @SpringBootApplication annotation	
19. Running your application	
19.1. Running from an IDE	
19.2. Running as a packaged application	. 38
19.3. Using the Maven plugin	
19.4. Using the Gradle plugin	
19.5. Hot swapping	
20. Developer tools	
20.1. Property defaults	
20.2. Automatic restart	
Excluding resources	
Watching additional paths	
Disabling restart	
Using a trigger file	
Customizing the restart classloader	
Known limitations	
20.3. LiveReload	
20.4. Global settings	
20.5. Remote applications	
Running the remote client application	
Remote update	
Remote debug tunnel	
21. Packaging your application for production	
22. What to read next	
IV. Spring Boot features	
23. SpringApplication	
23.1. Customizing the Banner	
23.2. Customizing SpringApplication	
23.3. Fluent builder API	
23.4. Application events and listeners	. 52
23.5. Web environment	. 53
23.6. Accessing application arguments	. 53
23.7. Using the ApplicationRunner or CommandLineRunner	. 54
23.8. Application exit	. 54
23.9. Admin features	. 54
24. Externalized Configuration	. 55
24.1. Configuring random values	56
24.2. Accessing command line properties	56
24.3. Application property files	
24.4. Profile-specific properties	
24.5. Placeholders in properties	
24.6. Using YAML instead of Properties	

Loading YAML	58
Exposing YAML as properties in the Spring Environment	59
Multi-profile YAML documents	59
YAML shortcomings	60
24.7. Type-safe Configuration Properties	60
Third-party configuration	61
Relaxed binding	62
Properties conversion	62
@ConfigurationProperties Validation	63
25. Profiles	64
25.1. Adding active profiles	64
25.2. Programmatically setting profiles	
25.3. Profile-specific configuration files	
26. Logging	
26.1. Log format	
26.2. Console output	
Color-coded output	
26.3. File output	
26.4. Log Levels	
26.5. Custom log configuration	
26.6. Logback extensions	
Profile-specific configuration	
Environment properties	
27. Developing web applications	
27.1. The 'Spring Web MVC framework'	
Spring MVC auto-configuration	
HttpMessageConverters	
MessageCodesResolver	
Static Content	
ConfigurableWebBindingInitializer	
Template engines	
Error Handling	
Error Handling on WebSphere Application Server	
Spring HATEOAS	
CORS support	
27.2. JAX-RS and Jersey	
27.3. Embedded servlet container support	
Servlets, Filters, and listeners	
Registering Servlets, Filters, and listeners as Spring beans	
Servlet Context Initialization	
Scanning for Servlets, Filters, and listeners	
The EmbeddedWebApplicationContext	
Customizing embedded servlet containers	
Programmatic customization	
Customizing ConfigurableEmbeddedServletContainer directly	
JSP limitations	
28. Security	
28.1. OAuth2	
Authorization Server	
Resource Server	83

28.2. Token Type in User Info	
28.3. Customizing the User Info RestTemplate	. 84
Client	. 84
Single Sign On	. 85
28.4. Actuator Security	. 86
29. Working with SQL databases	87
29.1. Configure a DataSource	. 87
Embedded Database Support	. 87
Connection to a production database	. 88
Connection to a JNDI DataSource	. 89
29.2. Using JdbcTemplate	. 89
29.3. JPA and 'Spring Data'	. 89
Entity Classes	. 90
Spring Data JPA Repositories	. 90
Creating and dropping JPA databases	. 91
29.4. Using H2's web console	. 91
Changing the H2 console's path	. 92
Securing the H2 console	. 92
30. Using jOOQ	. 93
30.1. Code Generation	. 93
30.2. Using DSLContext	
30.3. Customizing jOOQ	
31. Working with NoSQL technologies	
31.1. Redis	
Connecting to Redis	
31.2. MongoDB	
Connecting to a MongoDB database	
MongoTemplate	
Spring Data MongoDB repositories	
Embedded Mongo	
31.3. Gemfire	
31.4. Solr	
Connecting to Solr	
Spring Data Solr repositories	
31.5. Elasticsearch	
Connecting to Elasticsearch	
Spring Data Elasticsearch repositories	
31.6. Cassandra	
Connecting to Cassandra	
Spring Data Cassandra repositories	
32. Caching	
32.1. Supported cache providers	101
Generic	
JCache	102
EhCache 2.x	
Hazelcast	
Infinispan	103
Redis	
Guava	
Simple	104

33. Messaging	105
33.1. JMS	105
ActiveMQ support	. 105
Artemis support	105
HornetQ support	. 105
Using a JNDI ConnectionFactory	106
Sending a message	106
Receiving a message	107
33.2. AMQP	108
RabbitMQ support	108
Sending a message	108
Receiving a message	109
34. Sending email	110
35. Distributed Transactions with JTA	111
35.1. Using an Atomikos transaction manager	111
35.2. Using a Bitronix transaction manager	111
35.3. Using a Java EE managed transaction manager	112
35.4. Mixing XA and non-XA JMS connections	112
35.5. Supporting an alternative embedded transaction manager	112
36. Hazelcast	113
37. Spring Integration	114
38. Spring Session	115
39. Monitoring and management over JMX	116
40. Testing	. 117
40.1. Test scope dependencies	117
40.2. Testing Spring applications	117
40.3. Testing Spring Boot applications	117
Using Spock to test Spring Boot applications	119
40.4. Test utilities	
ConfigFileApplicationContextInitializer	. 119
EnvironmentTestUtils	119
OutputCapture	. 119
TestRestTemplate	120
41. Creating your own auto-configuration	121
41.1. Understanding auto-configured beans	121
41.2. Locating auto-configuration candidates	121
41.3. Condition annotations	121
Class conditions	122
Bean conditions	122
Property conditions	. 122
Resource conditions	122
Web application conditions	
SpEL expression conditions	
41.4. Creating your own starter	
Naming	
Autoconfigure module	
Starter module	
42. WebSockets	
43. What to read next	
Spring Boot Actuator: Production-ready features	
· ·	

44. Enabling production-ready features	128
45. Endpoints	129
45.1. Customizing endpoints	130
45.2. Hypermedia for actuator MVC endpoints	130
45.3. CORS support	131
45.4. Adding custom endpoints	131
45.5. Health information	131
45.6. Security with HealthIndicators	
Auto-configured HealthIndicators	132
Writing custom HealthIndicators	
45.7. Custom application info information	
Automatically expand info properties at build time	133
Automatic property expansion using Maven	
Automatic property expansion using Gradle	
Git commit information	
46. Monitoring and management over HTTP	
46.1. Securing sensitive endpoints	
46.2. Customizing the management endpoint paths	
46.3. Customizing the management server port	
46.4. Customizing the management server address	
46.5. Disabling HTTP endpoints	
46.6. HTTP health endpoint access restrictions	
47. Monitoring and management over JMX	
47.1. Customizing MBean names	
47.2. Disabling JMX endpoints	
47.3. Using Jolokia for JMX over HTTP	
Customizing Jolokia	
Disabling Jolokia	
48. Monitoring and management using a remote shell	
48.1. Connecting to the remote shell	
Remote shell credentials	
48.2. Extending the remote shell	
Remote shell commands	
Remote shell plugins	
49. Metrics	
49.1. System metrics	
49.2. DataSource metrics	
49.3. Cache metrics	
49.4. Tomcat session metrics	
49.5. Recording your own metrics	
49.6. Adding your own public metrics	
49.7. Special features with Java 8	
49.8. Metric writers, exporters and aggregation	
Example: Export to Redis	
Example: Export to Open TSDB	
Example: Export to Statsd	
Example: Export to JMX	
49.9. Aggregating metrics from multiple sources	
49.10. Dropwizard Metrics	
49.11. Message channel integration	149

50. Auditing	150
51. Tracing	. 151
51.1. Custom tracing	. 151
52. Process monitoring	. 152
52.1. Extend configuration	. 152
52.2. Programmatically	. 152
53. What to read next	. 153
VI. Deploying Spring Boot applications	. 154
54. Deploying to the cloud	155
54.1. Cloud Foundry	155
Binding to services	. 156
54.2. Heroku	. 156
54.3. OpenShift	. 158
54.4. Boxfuse and Amazon Web Services	. 158
54.5. Google App Engine	. 159
55. Installing Spring Boot applications	. 160
55.1. Unix/Linux services	. 160
Installation as an init.d service (System V)	. 160
Securing an init.d service	. 161
Installation as a systemd service	. 161
Customizing the startup script	. 162
Customizing the startup script with a conf file	
56. Microsoft Windows services	
57. What to read next	. 165
VII. Spring Boot CLI	. 166
58. Installing the CLI	
59. Using the CLI	
59.1. Running applications using the CLI	
Deduced "grab" dependencies	
Deduced "grab" coordinates	170
Default import statements	
Automatic main method	. 170
Custom dependency management	. 170
59.2. Testing your code	171
59.3. Applications with multiple source files	
59.4. Packaging your application	. 171
59.5. Initialize a new project	. 172
59.6. Using the embedded shell	. 172
59.7. Adding extensions to the CLI	. 173
60. Developing application with the Groovy beans DSL	. 174
61. Configuring the CLI with settings.xml	
62. What to read next	
VIII. Build tool plugins	
63. Spring Boot Maven plugin	
63.1. Including the plugin	
63.2. Packaging executable jar and war files	
64. Spring Boot Gradle plugin	
64.1. Including the plugin	
64.2. Gradle dependency management	
64.3. Packaging executable jar and war files	
,	

	64.4. Running a project in-place	
	64.5. Spring Boot plugin configuration	
	64.6. Repackage configuration	
	64.7. Repackage with custom Gradle configuration	
	Configuration options	
	64.8. Understanding how the Gradle plugin works	
	64.9. Publishing artifacts to a Maven repository using Gradle	
	Configuring Gradle to produce a pom that inherits dependency management	
	Configuring Gradle to produce a pom that imports dependency management	185
	65. Spring Boot AntLib module	187
	65.1. Spring Boot Ant tasks	. 187
	spring-boot:exejar	. 187
	Examples	. 187
	65.2. spring-boot:findmainclass	188
	Examples	. 188
	66. Supporting other build systems	189
	66.1. Repackaging archives	. 189
	66.2. Nested libraries	189
	66.3. Finding a main class	. 189
	66.4. Example repackage implementation	189
	67. What to read next	190
IX.	'How-to' guides	191
	68. Spring Boot application	. 192
	68.1. Troubleshoot auto-configuration	. 192
	68.2. Customize the Environment or ApplicationContext before it starts	192
	68.3. Build an ApplicationContext hierarchy (adding a parent or root context)	
	68.4. Create a non-web application	
	69. Properties & configuration	
	69.1. Externalize the configuration of SpringApplication	194
	69.2. Change the location of external properties of an application	194
	69.3. Use 'short' command line arguments	
	69.4. Use YAML for external properties	
	69.5. Set the active Spring profiles	
	69.6. Change configuration depending on the environment	
	69.7. Discover built-in options for external properties	
	70. Embedded servlet containers	
	70.1. Add a Servlet, Filter or Listener to an application	
	Add a Servlet, Filter or Listener using a Spring bean	
	Disable registration of a Servlet or Filter	
	Add Servlets, Filters, and Listeners using classpath scanning	
	70.2. Change the HTTP port	
	70.3. Use a random unassigned HTTP port	
	70.4. Discover the HTTP port at runtime	
	70.5. Configure SSL	
	70.6. Configure Access Logging	
	70.7. Use behind a front-end proxy server	
	Customize Tomcat's proxy configuration	
	70.8. Configure Tomcat	
	70.9. Enable Multiple Connectors with Tomcat	
	70.10. Use Jetty instead of Tomcat	

70.11. Configure Jetty	202
70.12. Use Undertow instead of Tomcat	. 203
70.13. Configure Undertow	203
70.14. Enable Multiple Listeners with Undertow	203
70.15. Use Tomcat 7	. 204
Use Tomcat 7 with Maven	204
Use Tomcat 7 with Gradle	204
70.16. Use Jetty 8	. 204
Use Jetty 8 with Maven	204
Use Jetty 8 with Gradle	205
70.17. Create WebSocket endpoints using @ServerEndpoint	205
70.18. Enable HTTP response compression	205
71. Spring MVC	206
71.1. Write a JSON REST service	
71.2. Write an XML REST service	206
71.3. Customize the Jackson ObjectMapper	206
71.4. Customize the @ResponseBody rendering	
71.5. Handling Multipart File Uploads	
71.6. Switch off the Spring MVC DispatcherServlet	
71.7. Switch off the Default MVC configuration	
71.8. Customize ViewResolvers	
71.9. Velocity	
72. Logging	
72.1. Configure Logback for logging	
Configure logback for file only output	
72.2. Configure Log4j for logging	
Use YAML or JSON to configure Log4j 2	
73. Data Access	
73.1. Configure a DataSource	
73.2. Configure Two DataSources	
73.3. Use Spring Data repositories	
73.4. Separate @Entity definitions from Spring configuration	
73.5. Configure JPA properties	
73.6. Use a custom EntityManagerFactory	
73.7. Use Two EntityManagers	
73.8. Use a traditional persistence.xml	
73.9. Use Spring Data JPA and Mongo repositories	
73.10. Expose Spring Data repositories as REST endpoint	
74. Database initialization	
74.1. Initialize a database using JPA	
74.2. Initialize a database using Hibernate	
74.3. Initialize a database using Spring JDBC	
74.4. Initialize a Spring Batch database	
74.5. Use a higher level database migration tool	
Execute Flyway database migrations on startup	
Execute Liquibase database migrations on startup	
75. Batch applications	
75.1. Execute Spring Batch jobs on startup	
76. Actuator	
76.1. Change the HTTP port or address of the actuator endpoints	222

	222
76.3. Actuator and Jersey	222
77. Security	223
77.1. Switch off the Spring Boot security configuration	223
77.2. Change the AuthenticationManager and add user accounts	223
77.3. Enable HTTPS when running behind a proxy server	223
78. Hot swapping	225
78.1. Reload static content	225
78.2. Reload templates without restarting the container	225
Thymeleaf templates	225
FreeMarker templates	225
Groovy templates	225
Velocity templates	225
78.3. Fast application restarts	225
78.4. Reload Java classes without restarting the container	225
Configuring Spring Loaded for use with Maven	226
Configuring Spring Loaded for use with Gradle and IntelliJ IDEA	226
79. Build	227
79.1. Customize dependency versions	227
79.2. Create an executable JAR with Maven	227
79.3. Create an additional executable JAR	228
79.4. Extract specific libraries when an executable jar runs	228
79.5. Create a non-executable JAR with exclusions	229
79.6. Remote debug a Spring Boot application started with Maven	230
79.7. Remote debug a Spring Boot application started with Gradle	230
79.8. Build an executable archive from Ant without using spring-boot-antlib	230
79.9. How to use Java 6	231
Embedded servlet container compatibility	231
JTA API compatibility	231
80. Traditional deployment	
	232
80. Traditional deployment	232 232
80. Traditional deployment	232 232 233
80. Traditional deployment 80.1. Create a deployable war file 80.2. Create a deployable war file for older servlet containers	232 232 233 233
 80. Traditional deployment 80.1. Create a deployable war file 80.2. Create a deployable war file for older servlet containers 80.3. Convert an existing application to Spring Boot 	232 232 233 233 234
 80. Traditional deployment 80.1. Create a deployable war file 80.2. Create a deployable war file for older servlet containers 80.3. Convert an existing application to Spring Boot 80.4. Deploying a WAR to WebLogic 	232 232 233 233 234 235

D. The executable jar format	271
D.1. Nested JARs	271
The executable jar file structure	271
The executable war file structure	271
D.2. Spring Boot's "JarFile" class	. 272
Compatibility with the standard Java "JarFile"	272
D.3. Launching executable jars	. 272
Launcher manifest	. 273
Exploded archives	. 273
D.4. PropertiesLauncher Features	. 273
D.5. Executable jar restrictions	274
Zip entry compression	274
System ClassLoader	274
D.6. Alternative single jar solutions	275
E. Dependency versions	. 276

Part I. Spring Boot Documentation

This section provides a brief overview of Spring Boot reference documentation. Think of it as map for the rest of the document. You can read this reference guide in a linear fashion, or you can skip sections if something doesn't interest you.

1. About the documentation

The Spring Boot reference guide is available as <u>html</u>, <u>pdf</u> and <u>epub</u> documents. The latest copy is available at <u>docs.spring.io/spring-boot/docs/current/reference</u>.

Copies of this document may be made for your own use and for distribution to others, provided that you do not charge any fee for such copies and further provided that each copy contains this Copyright Notice, whether distributed in print or electronically.

2. Getting help

Having trouble with Spring Boot, We'd like to help!

- Try the <u>How-to's</u> they provide solutions to the most common questions.
- Learn the Spring basics Spring Boot builds on many other Spring projects, check the <u>spring.io</u> website for a wealth of reference documentation. If you are just starting out with Spring, try one of the <u>guides</u>.
- Ask a question we monitor <u>stackoverflow.com</u> for questions tagged with <u>spring-boot</u>.
- Report bugs with Spring Boot at github.com/spring-projects/spring-boot/issues.

Note

All of Spring Boot is open source, including the documentation! If you find problems with the docs; or if you just want to improve them, please <u>get involved</u>.

3. First steps

If you're just getting started with Spring Boot, or 'Spring' in general, this is the place to start!

- From scratch: Overview | Requirements | Installation
- Tutorial: Part 1 | Part 2
- Running your example: Part 1 | Part 2

4. Working with Spring Boot

Ready to actually start using Spring Boot? We've got you covered.

- Build systems: <u>Maven | Gradle | Ant | Starter POMs</u>
- Best practices: <u>Code Structure</u> | <u>@Configuration</u> | <u>@EnableAutoConfiguration</u> | <u>Beans and</u> <u>Dependency Injection</u>
- Running your code IDE | Packaged | Maven | Gradle
- Packaging your app: Production jars
- Spring Boot CLI: Using the CLI

5. Learning about Spring Boot features

Need more details about Spring Boot's core features? This is for you!

- Core Features: <u>SpringApplication</u> | <u>External Configuration</u> | <u>Profiles</u> | <u>Logging</u>
- Web Applications: <u>MVC</u> | <u>Embedded Containers</u>
- Working with data: <u>SQL</u> | <u>NO-SQL</u>

6. Moving to production

When you're ready to push your Spring Boot application to production, we've got <u>some tricks that you</u> <u>might like</u>!

- Management endpoints: Overview | Customization
- Connection options: <u>HTTP | JMX | SSH</u>
- Monitoring: <u>Metrics</u> | <u>Auditing</u> | <u>Tracing</u> | <u>Process</u>

7. Advanced topics

Lastly, we have a few topics for the more advanced user.

- Deploy Spring Boot Applications: <u>Cloud Deployment | OS Service</u>
- Build tool plugins: Maven | Gradle
- Appendix: <u>Application Properties</u> | <u>Auto-configuration classes</u> | <u>Executable Jars</u>

Part II. Getting started

If you're just getting started with Spring Boot, or 'Spring' in general, this is the section for you! Here we answer the basic "what?", "how?" and "why?" questions. You'll find a gentle introduction to Spring Boot along with installation instructions. We'll then build our first Spring Boot application, discussing some core principles as we go.

8. Introducing Spring Boot

Spring Boot makes it easy to create stand-alone, production-grade Spring based Applications that you can "just run". We take an opinionated view of the Spring platform and third-party libraries so you can get started with minimum fuss. Most Spring Boot applications need very little Spring configuration.

You can use Spring Boot to create Java applications that can be started using java -jar or more traditional war deployments. We also provide a command line tool that runs "spring scripts".

Our primary goals are:

- Provide a radically faster and widely accessible getting started experience for all Spring development.
- Be opinionated out of the box, but get out of the way quickly as requirements start to diverge from the defaults.
- Provide a range of non-functional features that are common to large classes of projects (e.g. embedded servers, security, metrics, health checks, externalized configuration).
- Absolutely no code generation and no requirement for XML configuration.

9. System Requirements

By default, Spring Boot 1.3.3.RELEASE requires <u>Java 7</u> and Spring Framework 4.1.5 or above. You can use Spring Boot with Java 6 with some additional configuration. See <u>Section 79.9</u>, "How to use Java 6" for more details. Explicit build support is provided for Maven (3.2+) and Gradle (1.12+).

Тір

Although you can use Spring Boot with Java 6 or 7, we generally recommend Java 8 if at all possible.

9.1 Servlet containers

The following embedded servlet containers are supported out of the box:

Name	Servlet Version	Java Version
Tomcat 8	3.1	Java 7+
Tomcat 7	3.0	Java 6+
Jetty 9	3.1	Java 7+
Jetty 8	3.0	Java 6+
Undertow 1.1	3.1	Java 7+

You can also deploy Spring Boot applications to any Servlet 3.0+ compatible container.

10. Installing Spring Boot

Spring Boot can be used with "classic" Java development tools or installed as a command line tool. Regardless, you will need <u>Java SDK v1.6</u> or higher. You should check your current Java installation before you begin:

\$ java -version

If you are new to Java development, or if you just want to experiment with Spring Boot you might want to try the <u>Spring Boot CLI</u> first, otherwise, read on for "classic" installation instructions.

Тір

Although Spring Boot is compatible with Java 1.6, if possible, you should consider using the latest version of Java.

10.1 Installation instructions for the Java developer

You can use Spring Boot in the same way as any standard Java library. Simply include the appropriate spring-boot-*.jar files on your classpath. Spring Boot does not require any special tools integration, so you can use any IDE or text editor; and there is nothing special about a Spring Boot application, so you can run and debug as you would any other Java program.

Although you *could* just copy Spring Boot jars, we generally recommend that you use a build tool that supports dependency management (such as Maven or Gradle).

Maven installation

Spring Boot is compatible with Apache Maven 3.2 or above. If you don't already have Maven installed you can follow the instructions at <u>maven.apache.org</u>.

Тір

On many operating systems Maven can be installed via a package manager. If you're an OSX Homebrew user try brew install maven. Ubuntu users can run sudo apt-get install maven.

Spring Boot dependencies use the org.springframework.boot groupId. Typically your Maven POM file will inherit from the spring-boot-starter-parent project and declare dependencies to one or more <u>"Starter POMs"</u>. Spring Boot also provides an optional <u>Maven plugin</u> to create executable jars.

Here is a typical pom.xml file:

```
<groupId>org.springframework.boot</groupId>
   <artifactId>spring-boot-starter-parent</artifactId>
   <version>1.3.3.RELEASE</version>
</parent>
<!-- Add typical dependencies for a web application -->
<dependencies>
   <dependency>
       <groupId>org.springframework.boot</groupId>
       <artifactId>spring-boot-starter-web</artifactId>
   </dependency>
</dependencies>
<!-- Package as an executable jar -->
<build>
   <plugins>
       <plugin>
           <groupId>org.springframework.boot</groupId>
            <artifactId>spring-boot-maven-plugin</artifactId>
       </plugin>
   </plugins>
</build>
```

</project>

Тір

The spring-boot-starter-parent is a great way to use Spring Boot, but it might not be suitable all of the time. Sometimes you may need to inherit from a different parent POM, or you might just not like our default settings. See <u>the section called "Using Spring Boot without the parent POM"</u> for an alternative solution that uses an import scope.

Gradle installation

Spring Boot is compatible with Gradle 1.12 or above. If you don't already have Gradle installed you can follow the instructions at <u>www.gradle.org/</u>.

Spring Boot dependencies can be declared using the org.springframework.boot group. Typically your project will declare dependencies to one or more <u>"Starter POMs"</u>. Spring Boot provides a useful <u>Gradle plugin</u> that can be used to simplify dependency declarations and to create executable jars.

Gradle Wrapper

The Gradle Wrapper provides a nice way of "obtaining" Gradle when you need to build a project. It's a small script and library that you commit alongside your code to bootstrap the build process. See www.gradle.org/docs/current/userguide/gradle_wrapper.html for details.

Here is a typical build.gradle file:

```
buildscript {
    repositories {
        jcenter()
        maven { url "http://repo.spring.io/snapshot" }
        maven { url "http://repo.spring.io/milestone" }
    }
    dependencies {
        classpath("org.springframework.boot:spring-boot-gradle-plugin:1.3.3.RELEASE")
    }
}
apply plugin: 'java'
apply plugin: 'java'
```

```
jar {
   baseName = 'myproject'
   version = '0.0.1-SNAPSHOT'
}
repositories {
   jcenter()
   maven { url "http://repo.spring.io/snapshot" }
   maven { url "http://repo.spring.io/milestone" }
}
dependencies {
   compile("org.springframework.boot:spring-boot-starter-web")
   testCompile("org.springframework.boot:spring-boot-starter-test")
}
```

10.2 Installing the Spring Boot CLI

The Spring Boot CLI is a command line tool that can be used if you want to quickly prototype with Spring. It allows you to run <u>Groovy</u> scripts, which means that you have a familiar Java-like syntax, without so much boilerplate code.

You don't need to use the CLI to work with Spring Boot but it's definitely the quickest way to get a Spring application off the ground.

Manual installation

You can download the Spring CLI distribution from the Spring software repository:

- spring-boot-cli-1.3.3.RELEASE-bin.zip
- spring-boot-cli-1.3.3.RELEASE-bin.tar.gz

Cutting edge snapshot distributions are also available.

Once downloaded, follow the <u>INSTALL.txt</u> instructions from the unpacked archive. In summary: there is a spring script (spring.bat for Windows) in a bin/ directory in the .zip file, or alternatively you can use java -jar with the .jar file (the script helps you to be sure that the classpath is set correctly).

Installation with SDKMAN!

SDKMAN! (The Software Development Kit Manager) can be used for managing multiple versions of various binary SDKs, including Groovy and the Spring Boot CLI. Get SDKMAN! from <u>sdkman.io</u> and install Spring Boot with

```
$ sdk install springboot
$ spring --version
Spring Boot v1.3.3.RELEASE
```

If you are developing features for the CLI and want easy access to the version you just built, follow these extra instructions.

```
$ sdk install springboot dev /path/to/spring-boot/spring-boot-cli/target/spring-boot-cli-1.3.3.RELEASE-
bin/spring-1.3.3.RELEASE/
$ sdk default springboot dev
$ spring --version
Spring CLI v1.3.3.RELEASE
```

This will install a local instance of spring called the dev instance. It points at your target build location, so every time you rebuild Spring Boot, spring will be up-to-date.

You can see it by doing this:

\$ sdk ls springboot	
	===
Available Springboot Versions	
	===
> + dev	
* 1.3.3.RELEASE	
	===
+ - local version	
* - installed	
> - currently in use	
	===

OSX Homebrew installation

If you are on a Mac and using Homebrew, all you need to do to install the Spring Boot CLI is:

```
$ brew tap pivotal/tap
$ brew install springboot
```

Homebrew will install spring to /usr/local/bin.

Note

If you don't see the formula, your installation of brew might be out-of-date. Just execute brew update and try again.

MacPorts installation

If you are on a Mac and using MacPorts, all you need to do to install the Spring Boot CLI is:

\$ sudo port install spring-boot-cli

Command-line completion

Spring Boot CLI ships with scripts that provide command completion for <u>BASH</u> and <u>zsh</u> shells. You can source the script (also named spring) in any shell, or put it in your personal or system-wide bash completion initialization. On a Debian system the system-wide scripts are in /shell-completion/ bash and all scripts in that directory are executed when a new shell starts. To run the script manually, e.g. if you have installed using SDKMAN!

```
$ . ~/.sdkman/springboot/current/shell-completion/bash/spring
$ spring <HIT TAB HERE>
  grab help jar run test version
```

Note

If you install Spring Boot CLI using Homebrew or MacPorts, the command-line completion scripts are automatically registered with your shell.

Quick start Spring CLI example

Here's a really simple web application that you can use to test your installation. Create a file called app.groovy:

```
@RestController
class ThisWillActuallyRun {
    @RequestMapping("/")
    String home() {
        "Hello World!"
    }
}
```

Then simply run it from a shell:

```
$ spring run app.groovy
```

Note

It will take some time when you first run the application as dependencies are downloaded. Subsequent runs will be much quicker.

Open localhost:8080 in your favorite web browser and you should see the following output:

Hello World!

10.3 Upgrading from an earlier version of Spring Boot

If you are upgrading from an earlier release of Spring Boot check the "release notes" hosted on the <u>project wiki</u>. You'll find upgrade instructions along with a list of "new and noteworthy" features for each release.

To upgrade an existing CLI installation use the appropriate package manager command (for example brew upgrade) or, if you manually installed the CLI, follow the <u>standard instructions</u> remembering to update your PATH environment variable to remove any older references.

11. Developing your first Spring Boot application

Let's develop a simple "Hello World!" web application in Java that highlights some of Spring Boot's key features. We'll use Maven to build this project since most IDEs support it.

Тір

The <u>spring.io</u> web site contains many "Getting Started" guides that use Spring Boot. If you're looking to solve a specific problem; check there first.

You can shortcut the steps below by going to <u>start.spring.io</u> and choosing the web starter from the dependencies searcher. This will automatically generate a new project structure so that you can <u>start coding right the way</u>. Check the <u>documentation for more details</u>.

Before we begin, open a terminal to check that you have valid versions of Java and Maven installed.

```
$ java -version
java version "1.7.0_51"
Java(TM) SE Runtime Environment (build 1.7.0_51-b13)
Java HotSpot(TM) 64-Bit Server VM (build 24.51-b03, mixed mode)
```

```
$ mvn -v
```

```
Apache Maven 3.2.3 (33f8c3e1027c3ddde99d3cdebad2656a3le8fdf4; 2014-08-11T13:58:10-07:00)
Maven home: /Users/user/tools/apache-maven-3.1.1
Java version: 1.7.0_51, vendor: Oracle Corporation
```

Note

This sample needs to be created in its own folder. Subsequent instructions assume that you have created a suitable folder and that it is your "current directory".

11.1 Creating the POM

We need to start by creating a Maven pom.xml file. The pom.xml is the recipe that will be used to build your project. Open your favorite text editor and add the following:

```
<?xml version="1.0" encoding="UTF-8"?>
cyroject xmlns="http://maven.apache.org/POM/4.0.0" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://maven.apache.org/POM/4.0.0 http://maven.apache.org/xsd/maven-4.0.0.xsd">
    cmodelVersion>4.0.0
cyroupId>com.example</groupId>
    <artifactId>myproject</artifactId>
    <version>0.0.1-SNAPSHOT</version>

cyproupId>com.examples
<p
```

This should give you a working build, you can test it out by running mvn package (you can ignore the "jar will be empty - no content was marked for inclusion!" warning for now).

Note

At this point you could import the project into an IDE (most modern Java IDE's include built-in support for Maven). For simplicity, we will continue to use a plain text editor for this example.

11.2 Adding classpath dependencies

Spring Boot provides a number of "Starter POMs" that make easy to add jars to your classpath. Our sample application has already used spring-boot-starter-parent in the parent section of the POM. The spring-boot-starter-parent is a special starter that provides useful Maven defaults. It also provides a <u>dependency-management</u> section so that you can omit version tags for "blessed" dependencies.

Other "Starter POMs" simply provide dependencies that you are likely to need when developing a specific type of application. Since we are developing a web application, we will add a spring-boot-starter-web dependency — but before that, let's look at what we currently have.

```
$ mvn dependency:tree
[INFO] com.example:myproject:jar:0.0.1-SNAPSHOT
```

The mvn dependency:tree command prints a tree representation of your project dependencies. You can see that spring-boot-starter-parent provides no dependencies by itself. Let's edit our pom.xml and add the spring-boot-starter-web dependency just below the parent section:

```
<dependencies>
    <dependency>
        <groupId>org.springframework.boot</groupId>
        <artifactId>spring-boot-starter-web</artifactId>
        </dependency>
</dependencies>
```

If you run mvn dependency:tree again, you will see that there are now a number of additional dependencies, including the Tomcat web server and Spring Boot itself.

11.3 Writing the code

To finish our application we need to create a single Java file. Maven will compile sources from src/main/java by default so you need to create that folder structure, then add a file named src/main/java/Example.java:

```
import org.springframework.boot.*;
import org.springframework.boot.autoconfigure.*;
import org.springframework.stereotype.*;
import org.springframework.web.bind.annotation.*;
@RestController
@EnableAutoConfiguration
public class Example {
    @RequestMapping("/")
    String home() {
        return "Hello World!";
    }
    public static void main(String[] args) throws Exception {
        SpringApplication.run(Example.class, args);
    }
}
```

Although there isn't much code here, quite a lot is going on. Let's step through the important parts.

The @RestController and @RequestMapping annotations

The first annotation on our Example class is @RestController. This is known as a stereotype annotation. It provides hints for people reading the code, and for Spring, that the class plays a specific role. In this case, our class is a web @Controller so Spring will consider it when handling incoming web requests.

The @RequestMapping annotation provides "routing" information. It is telling Spring that any HTTP request with the path "/" should be mapped to the home method. The @RestController annotation tells Spring to render the resulting string directly back to the caller.

Тір

The @RestController and @RequestMapping annotations are Spring MVC annotations (they are not specific to Spring Boot). See the <u>MVC section</u> in the Spring Reference Documentation for more details.

The @EnableAutoConfiguration annotation

The second class-level annotation is @EnableAutoConfiguration. This annotation tells Spring Boot to "guess" how you will want to configure Spring, based on the jar dependencies that you have added. Since spring-boot-starter-web added Tomcat and Spring MVC, the auto-configuration will assume that you are developing a web application and setup Spring accordingly.

Starter POMs and Auto-Configuration

Auto-configuration is designed to work well with "Starter POMs", but the two concepts are not directly tied. You are free to pick-and-choose jar dependencies outside of the starter POMs and Spring Boot will still do its best to auto-configure your application.

The "main" method

The final part of our application is the main method. This is just a standard method that follows the Java convention for an application entry point. Our main method delegates to Spring Boot's SpringApplication class by calling run. SpringApplication will bootstrap our application, starting Spring which will in turn start the auto-configured Tomcat web server. We need to pass Example.class as an argument to the run method to tell SpringApplication which is the primary Spring component. The args array is also passed through to expose any command-line arguments.

11.4 Running the example

At this point our application should work. Since we have used the spring-boot-starter-parent
POM we have a useful run goal that we can use to start the application. Type mvn spring-boot:run
from the root project directory to start the application:

```
$ mvn spring-boot:run
```

If you open a web browser to localhost:8080 you should see the following output:

Hello World!

To gracefully exit the application hit ctrl-c.

11.5 Creating an executable jar

Let's finish our example by creating a completely self-contained executable jar file that we could run in production. Executable jars (sometimes called "fat jars") are archives containing your compiled classes along with all of the jar dependencies that your code needs to run.

Executable jars and Java

Java does not provide any standard way to load nested jar files (i.e. jar files that are themselves contained within a jar). This can be problematic if you are looking to distribute a self-contained application.

To solve this problem, many developers use "uber" jars. An uber jar simply packages all classes, from all jars, into a single archive. The problem with this approach is that it becomes hard to see which libraries you are actually using in your application. It can also be problematic if the same filename is used (but with different content) in multiple jars.

Spring Boot takes a different approach and allows you to actually nest jars directly.

To create an executable jar we need to add the spring-boot-maven-plugin to our pom.xml. Insert the following lines just below the dependencies section:

```
<build>
<plugins>
<plugin>
<groupId>org.springframework.boot</groupId>
<artifactId>spring-boot-maven-plugin</artifactId>
</plugin>
</plugins>
</build>
```

Note

The spring-boot-starter-parent POM includes <executions> configuration to bind the repackage goal. If you are not using the parent POM you will need to declare this configuration yourself. See the <u>plugin documentation</u> for details.

Save your pom.xml and run mvn package from the command line:

If you look in the target directory you should see myproject-0.0.1-SNAPSHOT.jar. The file should be around 10 Mb in size. If you want to peek inside, you can use jar tvf:

```
$ jar tvf target/myproject-0.0.1-SNAPSHOT.jar
```

You should also see a much smaller file named myproject-0.0.1-SNAPSHOT.jar.original in the target directory. This is the original jar file that Maven created before it was repackaged by Spring Boot.

To run that application, use the java -jar command:

As before, to gracefully exit the application hit ctrl-c.

12. What to read next

Hopefully this section has provided you with some of the Spring Boot basics, and got you on your way to writing your own applications. If you're a task-oriented type of developer you might want to jump over to <u>spring.io</u> and check out some of the <u>getting started</u> guides that solve specific "How do I do that with Spring" problems; we also have Spring Boot-specific <u>How-to</u> reference documentation.

The <u>Spring Boot repository</u> has also a <u>bunch of samples</u> you can run. The samples are independent of the rest of the code (that is you don't need to build the rest to run or use the samples).

Otherwise, the next logical step is to read <u>Part III, "Using Spring Boot</u>". If you're really impatient, you could also jump ahead and read about <u>Spring Boot features</u>.

Part III. Using Spring Boot

This section goes into more detail about how you should use Spring Boot. It covers topics such as build systems, auto-configuration and how to run your applications. We also cover some Spring Boot best practices. Although there is nothing particularly special about Spring Boot (it is just another library that you can consume), there are a few recommendations that, when followed, will make your development process just a little easier.

If you're just starting out with Spring Boot, you should probably read the <u>Getting Started</u> guide before diving into this section.

13. Build systems

It is strongly recommended that you choose a build system that supports <u>dependency management</u>, and one that can consume artifacts published to the "Maven Central" repository. We would recommend that you choose Maven or Gradle. It is possible to get Spring Boot to work with other build systems (Ant for example), but they will not be particularly well supported.

13.1 Dependency management

Each release of Spring Boot provides a curated list of dependencies it supports. In practice, you do not need to provide a version for any of these dependencies in your build configuration as Spring Boot is managing that for you. When you upgrade Spring Boot itself, these dependencies will be upgraded as well in a consistent way.

Note

You can still specify a version and override Spring Boot's recommendations if you feel that's necessary.

The curated list contains all the spring modules that you can use with Spring Boot as well as a refined list of third party libraries. The list is available as a standard <u>Bills of Materials (spring-boot-dependencies</u>) and additional dedicated support for <u>Maven</u> and <u>Gradle</u> are available as well.

Warning

Each release of Spring Boot is associated with a base version of the Spring Framework so we **highly** recommend you to not specify its version on your own.

13.2 Maven

Maven users can inherit from the spring-boot-starter-parent project to obtain sensible defaults. The parent project provides the following features:

- Java 1.6 as the default compiler level.
- UTF-8 source encoding.
- A <u>Dependency Management section</u>, allowing you to omit <version> tags for common dependencies, inherited from the spring-boot-dependencies POM.
- Sensible resource filtering.
- Sensible plugin configuration (exec plugin, surefire, Git commit ID, shade).
- Sensible resource filtering for application.properties and application.yml

On the last point: since the default config files accept Spring style placeholders ($\{\dots\}$) the Maven filtering is changed to use @..@ placeholders (you can override that with a Maven property resource.delimiter).

Inheriting the starter parent

To configure your project to inherit from the spring-boot-starter-parent simply set the parent:

Note

You should only need to specify the Spring Boot version number on this dependency. If you import additional starters, you can safely omit the version number.

With that setup, you can also override individual dependencies by overriding a property in your own project. For instance, to upgrade to another Spring Data release train you'd add the following to your pom.xml.

```
<properties>
    <properties>
    <properties>
    <properties>
    </properties>
</properties>
</properties>
```

Tip

Check the <u>spring-boot-dependencies</u> pom for a list of supported properties.

Using Spring Boot without the parent POM

Not everyone likes inheriting from the spring-boot-starter-parent POM. You may have your own corporate standard parent that you need to use, or you may just prefer to explicitly declare all your Maven configuration.

If you don't want to use the spring-boot-starter-parent, you can still keep the benefit of the dependency management (but not the plugin management) by using a scope=import dependency:

```
<dependencyManagement>

<dependencies>

<dependency>

<!-- Import dependency management from Spring Boot -->

<groupId>org.springframework.boot</groupId>

<artifactId>spring-boot-dependencies</artifactId>

<version>1.3.3.RELEASE</version>

<type>pom</type>

<scope>import</scope>

</dependency>

</dependencies>

</dependencies>
```

That setup does not allow you to override individual dependencies using a property as explained above. To achieve the same result, you'd need to add an entry in the dependencyManagement of your project **before** the spring-boot-dependencies entry. For instance, to upgrade to another Spring Data release train you'd add the following to your pom.xml.

```
<dependencyManagement>
    <dependencies>
        <!-- Override Spring Data release train provided by Spring Boot -->
        <dependency>
            <groupId>org.springframework.data</groupId>
                <artifactId>spring-data-releasetrain</artifactId>
                <version>Fowler-SR2</version>
                <scope>import</scope>
```

```
<type>pom</type>
</dependency>
<dependency>
<groupId>org.springframework.boot</groupId>
<artifactId>spring-boot-dependencies</artifactId>
<version>1.3.3.RELEASE</version>
<type>pom</type>
<scope>import</scope>
</dependency>
</dependencies>
</dependencies>
```

Note

In the example above, we specify a BOM but any dependency type can be overridden that way.

Changing the Java version

The spring-boot-starter-parent chooses fairly conservative Java compatibility. If you want to follow our recommendation and use a later Java version you can add a java.version property:

```
<properties>
<java.version>1.8</java.version>
</properties>
```

Using the Spring Boot Maven plugin

Spring Boot includes a <u>Maven plugin</u> that can package the project as an executable jar. Add the plugin to your <plugins> section if you want to use it:

```
<build>
<plugins>
<plugin>
<groupId>org.springframework.boot</groupId>
<artifactId>spring-boot-maven-plugin</artifactId>
</plugin>
</plugins>
</build>
```

Note

If you use the Spring Boot starter parent pom, you only need to add the plugin, there is no need for to configure it unless you want to change the settings defined in the parent.

13.3 Gradle

Gradle users can directly import "starter POMs" in their dependencies section. Unlike Maven, there is no "super parent" to import to share some configuration.

```
apply plugin: 'java'
repositories {
    jcenter()
}
dependencies {
    compile("org.springframework.boot:spring-boot-starter-web:1.3.3.RELEASE")
}
```

The <u>spring-boot-gradle-plugin</u> is also available and provides tasks to create executable jars and run projects from source. It also provides <u>dependency management</u> that, among other capabilities, allows you to omit the version number for any dependencies that are managed by Spring Boot:

```
buildscript {
    repositories {
       jcenter()
    }
    dependencies {
       classpath("org.springframework.boot:spring-boot-gradle-plugin:1.3.3.RELEASE")
    }
}
apply plugin: 'java'
apply plugin: 'spring-boot'
repositories {
    jcenter()
}
dependencies {
    compile("org.springframework.boot:spring-boot-starter-web")
    testCompile("org.springframework.boot:spring-boot-starter-test")
}
```

13.4 Ant

It is possible to build a Spring Boot project using Apache Ant+Ivy. The spring-boot-antlib "AntLib" module is also available to help Ant create executable jars.

To declare dependencies a typical ivy.xml file will look something like this:

```
<ivy-module version="2.0">
    <info organisation="org.springframework.boot" module="spring-boot-sample-ant" />
    <configurations>
        <conf name="compile" description="everything needed to compile this module" />
        <conf name="runtime" extends="compile" description="everything needed to run this module" />
        <configurations>
        <dependencies>
        <dependency org="org.springframework.boot" name="spring-boot-starter"
        rev="${spring-boot.version}" conf="compile" />
        </dependencies>
    <//dependencies>
```

A typical build.xml will look like this:

```
<project

xmlns:ivy="antlib:org.apache.ivy.ant"

xmlns:spring-boot="antlib:org.springframework.boot.ant"

name="myapp" default="build">

<property name="spring-boot.version" value="1.3.0.BUILD-SNAPSHOT" />

<target name="resolve" description="--> retrieve dependencies with ivy">

<target apace apa
```

```
</target>

Тір

See the <u>Section 79.8, "Build an executable archive from Ant without using spring-boot-antlib"</u> "How-to" if you don't want to use the spring-boot-antlib module.

13.5 Starter POMs

Starter POMs are a set of convenient dependency descriptors that you can include in your application. You get a one-stop-shop for all the Spring and related technology that you need, without having to hunt through sample code and copy paste loads of dependency descriptors. For example, if you want to get started using Spring and JPA for database access, just include the spring-boot-starter-data-jpa dependency in your project, and you are good to go.

The starters contain a lot of the dependencies that you need to get a project up and running quickly and with a consistent, supported set of managed transitive dependencies.

What's in a name

All **official** starters follow a similar naming pattern; spring-boot-starter-*, where * is a particular type of application. This naming structure is intended to help when you need to find a starter. The Maven integration in many IDEs allow you to search dependencies by name. For example, with the appropriate Eclipse or STS plugin installed, you can simply hit ctrl-space in the POM editor and type "spring-boot-starter" for a complete list.

As explained in the <u>Creating your own starter</u> section, third party starters should not start with spring-boot as it is reserved for official Spring Boot artifacts. A third-party starter for acme will be typically named acme-spring-boot-starter.

The following application starters are provided by Spring Boot under the org.springframework.boot group:

Name	Description
spring-boot-starter	The core Spring Boot starter, including auto- configuration support, logging and YAML.
spring-boot-starter-actuator	Production ready features to help you monitor and manage your application.

Description
Support for the "Advanced Message Queuing Protocol" via spring-rabbit.
Support for aspect-oriented programming including spring-aop and AspectJ.
Support for "Java Message Service API" via Apache Artemis.
Support for "Spring Batch" including HSQLDB database.
Support for Spring's Cache abstraction.
Support for "Spring Cloud Connectors" which simplifies connecting to services in cloud platforms like Cloud Foundry and Heroku.
Support for the Elasticsearch search and analytics engine including spring-data-elasticsearch.
Support for the GemFire distributed data store including spring-data-gemfire.
Support for the "Java Persistence API" including spring-data-jpa, spring-orm and Hibernate.
Support for the MongoDB NoSQL Database, including spring-data-mongodb.
Support for exposing Spring Data repositories over REST via spring-data-rest-webmvc.
Support for the Apache Solr search platform, including spring-data-solr.
Support for the FreeMarker templating engine.
Support for the Groovy templating engine.
Support for HATEOAS-based RESTful services via spring-hateoas.
Support for "Java Message Service API" via HornetQ.
Support for common spring-integration modules.
Support for JDBC databases.
Support for the Jersey RESTful Web Services framework.

Name	Description
spring-boot-starter-jta-atomikos	Support for JTA distributed transactions via Atomikos.
spring-boot-starter-jta-bitronix	Support for JTA distributed transactions via Bitronix.
spring-boot-starter-mail	Support for javax.mail.
spring-boot-starter-mobile	Support for spring-mobile.
spring-boot-starter-mustache	Support for the Mustache templating engine.
spring-boot-starter-redis	Support for the REDIS key-value data store, including spring-redis.
spring-boot-starter-security	Support for spring-security.
spring-boot-starter-social-facebook	Support for spring-social-facebook.
spring-boot-starter-social-linkedin	Support for spring-social-linkedin.
spring-boot-starter-social-twitter	Support for spring-social-twitter.
spring-boot-starter-test	Support for common test dependencies, including JUnit, Hamcrest and Mockito along with the spring-test module.
spring-boot-starter-thymeleaf	Support for the Thymeleaf templating engine, including integration with Spring.
spring-boot-starter-velocity	Support for the Velocity templating engine.
spring-boot-starter-web	Support for full-stack web development, including Tomcat and spring-webmvc.
spring-boot-starter-websocket	Support for WebSocket development.
spring-boot-starter-ws	Support for Spring Web Services.

In addition to the application starters, the following starters can be used to add *production ready* features.

Table 13.2. Spring Boot production ready starters

Name	Description
spring-boot-starter-actuator	Adds production ready features such as metrics and monitoring.
spring-boot-starter-remote-shell	Adds remote ssh shell support.

Finally, Spring Boot includes some starters that can be used if you want to exclude or swap specific technical facets.

Table 13.3. Spring Boot technical starters

Name	Description
spring-boot-starter-jetty	Imports the Jetty HTTP engine (to be used as an alternative to Tomcat).
spring-boot-starter-log4j	Support the Log4J logging framework.
spring-boot-starter-logging	Import Spring Boot's default logging framework (Logback).
spring-boot-starter-tomcat	Import Spring Boot's default HTTP engine (Tomcat).
spring-boot-starter-undertow	Imports the Undertow HTTP engine (to be used as an alternative to Tomcat).

Тір

For a list of additional community contributed starter POMs, see the <u>README file</u> in the springboot-starters module on GitHub.

14. Structuring your code

Spring Boot does not require any specific code layout to work, however, there are some best practices that help.

14.1 Using the "default" package

When a class doesn't include a package declaration it is considered to be in the "default package". The use of the "default package" is generally discouraged, and should be avoided. It can cause particular problems for Spring Boot applications that use @ComponentScan, @EntityScan or @SpringBootApplication annotations, since every class from every jar, will be read.

Тір

We recommend that you follow Java's recommended package naming conventions and use a reversed domain name (for example, com.example.project).

14.2 Locating the main application class

We generally recommend that you locate your main application class in a root package above other classes. The @EnableAutoConfiguration annotation is often placed on your main class, and it implicitly defines a base "search package" for certain items. For example, if you are writing a JPA application, the package of the @EnableAutoConfiguration annotated class will be used to search for @Entity items.

Using a root package also allows the <code>@ComponentScan</code> annotation to be used without needing to specify a <code>basePackage</code> attribute. You can also use the <code>@SpringBootApplication</code> annotation if your main class is in the root package.

Here is a typical layout:

```
com
+- example
+- myproject
+- Application.java
|
+- domain
| +- Customer.java
| +- CustomerRepository.java
|
+- service
| +- CustomerService.java
|
+- web
+- CustomerController.java
```

The Application. java file would declare the main method, along with the basic @Configuration.

```
public class Application {
    public static void main(String[] args) {
        SpringApplication.run(Application.class, args);
    }
}
```

15. Configuration classes

Spring Boot favors Java-based configuration. Although it is possible to call SpringApplication.run() with an XML source, we generally recommend that your primary source is a @Configuration class. Usually the class that defines the main method is also a good candidate as the primary @Configuration.

Тір

Many Spring configuration examples have been published on the Internet that use XML configuration. Always try to use the equivalent Java-based configuration if possible. Searching for enable* annotations can be a good starting point.

15.1 Importing additional configuration classes

You don't need to put all your @Configuration into a single class. The @Import annotation can be used to import additional configuration classes. Alternatively, you can use @ComponentScan to automatically pick up all Spring components, including @Configuration classes.

15.2 Importing XML configuration

If you absolutely must use XML based configuration, we recommend that you still start with a @Configuration class. You can then use an additional @ImportResource annotation to load XML configuration files.

16. Auto-configuration

Spring Boot auto-configuration attempts to automatically configure your Spring application based on the jar dependencies that you have added. For example, If HSQLDB is on your classpath, and you have not manually configured any database connection beans, then we will auto-configure an in-memory database.

You need to opt-in to auto-configuration by adding the @EnableAutoConfiguration or @SpringBootApplication annotations to one of your @Configuration classes.

Тір

You should only ever add one @EnableAutoConfiguration annotation. We generally recommend that you add it to your primary @Configuration class.

16.1 Gradually replacing auto-configuration

Auto-configuration is noninvasive, at any point you can start to define your own configuration to replace specific parts of the auto-configuration. For example, if you add your own DataSource bean, the default embedded database support will back away.

If you need to find out what auto-configuration is currently being applied, and why, start your application with the --debug switch. This will log an auto-configuration report to the console.

16.2 Disabling specific auto-configuration

If you find that specific auto-configure classes are being applied that you don't want, you can use the exclude attribute of @EnableAutoConfiguration to disable them.

```
import org.springframework.boot.autoconfigure.*;
import org.springframework.boot.autoconfigure.jdbc.*;
import org.springframework.context.annotation.*;
@Configuration
@EnableAutoConfiguration(exclude={DataSourceAutoConfiguration.class})
public class MyConfiguration {
}
```

If the class is not on the classpath, you can use the excludeName attribute of the annotation and specify the fully qualified name instead. Finally, you can also control the list of auto-configuration classes to exclude via the spring.autoconfigure.exclude property.

Тір

You can define exclusions both at the annotation level and using the property.

17. Spring Beans and dependency injection

You are free to use any of the standard Spring Framework techniques to define your beans and their injected dependencies. For simplicity, we often find that using @ComponentScan to find your beans, in combination with @Autowired constructor injection works well.

If you structure your code as suggested above (locating your application class in a root package), you can add @ComponentScan without any arguments. All of your application components (@Component, @Service, @Repository, @Controller etc.) will be automatically registered as Spring Beans.

Here is an example @Service Bean that uses constructor injection to obtain a required RiskAssessor bean.

```
package com.example.service;
import org.springframework.beans.factory.annotation.Autowired;
import org.springframework.stereotype.Service;
@Service
public class DatabaseAccountService implements AccountService {
    private final RiskAssessor riskAssessor;
    @Autowired
    public DatabaseAccountService(RiskAssessor riskAssessor) {
        this.riskAssessor = riskAssessor;
    }
    // ...
}
```

Тір

Notice how using constructor injection allows the riskAssessor field to be marked as final, indicating that it cannot be subsequently changed.

18. Using the @SpringBootApplication annotation

Many Spring Boot developers always have their main class annotated with @Configuration, @EnableAutoConfiguration and @ComponentScan. Since these annotations are so frequently used together (especially if you follow the <u>best practices</u> above), Spring Boot provides a convenient @SpringBootApplication alternative.

The @SpringBootApplication annotation is equivalent to using @Configuration, @EnableAutoConfiguration and @ComponentScan with their default attributes:

```
package com.example.myproject;
import org.springframework.boot.SpringApplication;
import org.springframework.boot.autoconfigure.SpringBootApplication;
@SpringBootApplication // same as @Configuration @EnableAutoConfiguration @ComponentScan
public class Application {
    public static void main(String[] args) {
        SpringApplication.run(Application.class, args);
    }
}
```

Note

@SpringBootApplication also provides aliases to customize the attributes of @EnableAutoConfiguration and @ComponentScan.

19. Running your application

One of the biggest advantages of packaging your application as jar and using an embedded HTTP server is that you can run your application as you would any other. Debugging Spring Boot applications is also easy; you don't need any special IDE plugins or extensions.

Note

This section only covers jar based packaging, If you choose to package your application as a war file you should refer to your server and IDE documentation.

19.1 Running from an IDE

You can run a Spring Boot application from your IDE as a simple Java application, however, first you will need to import your project. Import steps will vary depending on your IDE and build system. Most IDEs can import Maven projects directly, for example Eclipse users can select Import... \rightarrow Existing Maven Projects from the File menu.

If you can't directly import your project into your IDE, you may be able to generate IDE metadata using a build plugin. Maven includes plugins for <u>Eclipse</u> and <u>IDEA</u>; Gradle offers plugins for <u>various IDEs</u>.

Тір

If you accidentally run a web application twice you will see a "Port already in use" error. STS users can use the Relaunch button rather than Run to ensure that any existing instance is closed.

19.2 Running as a packaged application

If you use the Spring Boot Maven or Gradle plugins to create an executable jar you can run your application using java -jar. For example:

\$ java -jar target/myproject-0.0.1-SNAPSHOT.jar

It is also possible to run a packaged application with remote debugging support enabled. This allows you to attach a debugger to your packaged application:

19.3 Using the Maven plugin

The Spring Boot Maven plugin includes a run goal which can be used to quickly compile and run your application. Applications run in an exploded form just like in your IDE.

\$ mvn spring-boot:run

You might also want to use the useful operating system environment variable:

\$ export MAVEN_OPTS=-Xmx1024m -XX:MaxPermSize=128M -Djava.security.egd=file:/dev/./urandom

(The "egd" setting is to speed up Tomcat startup by giving it a faster source of entropy for session keys.)

19.4 Using the Gradle plugin

The Spring Boot Gradle plugin also includes a bootRun task which can be used to run your application in an exploded form. The bootRun task is added whenever you import the spring-boot-gradle-plugin:

\$ gradle bootRun

You might also want to use this useful operating system environment variable:

```
$ export JAVA_OPTS=-Xmx1024m -XX:MaxPermSize=128M -Djava.security.egd=file:/dev/./urandom
```

19.5 Hot swapping

Since Spring Boot applications are just plain Java applications, JVM hot-swapping should work out of the box. JVM hot swapping is somewhat limited with the bytecode that it can replace, for a more complete solution <u>JRebel</u> or the <u>Spring Loaded</u> project can be used. The <u>spring-boot-devtools</u> module also includes support for quick application restarts.

See the Chapter 20, Developer tools section below and the Hot swapping "How-to" for details.

20. Developer tools

Spring Boot includes an additional set of tools that can make the application development experience a little more pleasant. The spring-boot-devtools module can be included in any project to provide additional development-time features. To include devtools support, simply add the module dependency to your build:

Maven.

```
<dependencies>
<dependency>
<groupId>org.springframework.boot</groupId>
<artifactId>spring-boot-devtools</artifactId>
<optional>true</optional>
</dependency>
</dependencies>
```

Gradle.

```
dependencies {
    compile("org.springframework.boot:spring-boot-devtools")
}
```

Note

Developer tools are automatically disabled when running a fully packaged application. If your application is launched using java -jar or if it's started using a special classloader, then it is considered a "production application". Flagging the dependency as optional is a best practice that prevents devtools from being transitively applied to other modules using your project. Gradle does not support optional dependencies out-of-the-box so you may want to have a look to the propdeps-plugin in the meantime.

Тір

If you want to ensure that devtools is never included in a production build, you can use the excludeDevtools build property to completely remove the JAR. The property is supported with both the Maven and Gradle plugins.

20.1 Property defaults

Several of the libraries supported by Spring Boot use caches to improve performance. For example, Thymeleaf will cache templates to save repeatedly parsing XML source files. Whilst caching is very beneficial in production, it can be counter productive during development. If you make a change to a template file in your IDE, you'll likely want to immediately see the result.

Cache options are usually configured by settings in your application.properties file. For example, Thymeleaf offers the spring.thymeleaf.cache property. Rather than needing to set these properties manually, the spring-boot-devtools module will automatically apply sensible development-time configuration.

Tip

For a complete list of the properties that are applied see <u>DevToolsPropertyDefaultsPostProcessor</u>.

20.2 Automatic restart

Applications that use spring-boot-devtools will automatically restart whenever files on the classpath change. This can be a useful feature when working in an IDE as it gives a very fast feedback loop for code changes. By default, any entry on the classpath that points to a folder will be monitored for changes. Note that certain resources such as static assets and view templates <u>do not need to restart the application</u>.

Triggering a restart

As DevTools monitors classpath resources, the only way to trigger a restart is to update the classpath. The way in which you cause the classpath to be updated depends on the IDE that you are using. In Eclipse, saving a modified file will cause the classpath to be updated and trigger a restart. In IntelliJ IDEA, building the project (Build # Make Project) will have the same effect.

Note

You can also start your application via the supported build plugins (i.e. Maven and Gradle) as long as forking is enabled since DevTools need an isolated application classloader to operate properly. You can force the plugin to fork the process as follows:

Maven.

```
<build>
<build>
<plugins>
<plugin>
<groupId>org.springframework.boot</groupId>
<artifactId>spring-boot-maven-plugin</artifactId>
<configuration>
<fork>true</fork>
</configuration>
</plugin>
</plugins>
</build>
```

Gradle.

```
bootRun {
    addResources = true
}
```

Tip

Automatic restart works very well when used with LiveReload. <u>See below</u> for details. If you use JRebel automatic restarts will be disabled in favor of dynamic class reloading. Other devtools features (such as LiveReload and property overrides) can still be used.

Note

DevTools relies on the application context's shutdown hook to close it during a restart. It will not work correctly if you have disabled the shutdown hook (SpringApplication.setRegisterShutdownHook(false)).

Note

When deciding if an entry on the classpath should trigger a restart when it changes, DevTools automatically ignores projects named spring-boot, spring-boot-devtools, spring-boot-autoconfigure, spring-boot-actuator, and spring-boot-starter.

Restart vs Reload

The restart technology provided by Spring Boot works by using two classloaders. Classes that don't change (for example, those from third-party jars) are loaded into a *base* classloader. Classes that you're actively developing are loaded into a *restart* classloader. When the application is restarted, the *restart* classloader is thrown away and a new one is created. This approach means that application restarts are typically much faster than "cold starts" since the *base* classloader is already available and populated.

If you find that restarts aren't quick enough for your applications, or you encounter classloading issues, you could consider reloading technologies such as <u>JRebel</u> from ZeroTurnaround. These work by rewriting classes as they are loaded to make them more amenable to reloading. <u>Spring</u> <u>Loaded</u> provides another option, however it doesn't support as many frameworks and it isn't commercially supported.

Excluding resources

Certain resources don't necessarily need to trigger a restart when they are changed. For example, Thymeleaf templates can just be edited in-place. By default changing resources in /META-INF/ maven, /META-INF/resources,/resources,/static,/public or /templates will not trigger a restart but will trigger a <u>live reload</u>. If you want to customize these exclusions you can use the spring.devtools.restart.exclude property. For example, to exclude only /static and / public you would set the following:

spring.devtools.restart.exclude=static/**,public/**

Тір

if you want to keep those defaults and *add* additional exclusions, use the spring.devtools.restart.additional-exclude property instead.

Watching additional paths

You may want your application to be restarted or reloaded when you make changes to files that are not on the classpath. To do so, use the spring.devtools.restart.additional-paths property to configure additional paths to watch for changes. You can use the spring.devtools.restart.exclude property <u>described above</u> to control whether changes beneath the additional paths will trigger a full restart or just a <u>live reload</u>.

Disabling restart

If you don't want to use the restart feature you can disable it using the spring.devtools.restart.enabled property. In most cases you can set this in your application.properties (this will still initialize the restart classloader but it won't watch for file changes).

If you need to *completely* disable restart support, for example, because it doesn't work with a specific library, you need to set a System property before calling SpringApplication.run(...). For example:

```
public static void main(String[] args) {
    System.setProperty("spring.devtools.restart.enabled", "false");
    SpringApplication.run(MyApp.class, args);
}
```

Using a trigger file

If you work with an IDE that continuously compiles changed files, you might prefer to trigger restarts only at specific times. To do this you can use a "trigger file", which is a special file that must be modified when you want to actually trigger a restart check. The trigger file could be updated manually, or via an IDE plugin.

To use a trigger file use the spring.devtools.restart.trigger-file property.

Тір

You might want to set spring.devtools.restart.trigger-file as a global setting so that all your projects behave in the same way.

Customizing the restart classloader

As described in the <u>Restart vs Reload</u> section above, restart functionality is implemented by using two classloaders. For most applications this approach works well, however, sometimes it can cause classloading issues.

By default, any open project in your IDE will be loaded using the "restart" classloader, and any regular . jar file will be loaded using the "base" classloader. If you work on a multi-module project, and not each module is imported into your IDE, you may need to customize things. To do this you can create a META-INF/spring-devtools.properties file.

The spring-devtools.properties file can contain restart.exclude. and restart.include. prefixed properties. The include elements are items that should be pulled up into the "restart" classloader, and the exclude elements are items that should be pushed down into the "base" classloader. The value of the property is a regex pattern that will be applied to the classpath.

For example:

```
restart.include.companycommonlibs=/mycorp-common-[\\w-]+\.jar
restart.include.projectcommon=/mycorp-myproj-[\\w-]+\.jar
```

Note

All property keys must be unique. As long as a property starts with restart.include. or restart.exclude. it will be considered.

Тір

All META-INF/spring-devtools.properties from the classpath will be loaded. You can package files inside your project, or in the libraries that the project consumes.

Known limitations

Restart functionality does not work well with objects that are deserialized using standard ObjectInputStream. lf you need to deserialize data. you а to use Spring's ConfigurableObjectInputStream with may need in combination Thread.currentThread().getContextClassLoader().

Unfortunately, several third-party libraries deserialize without considering the context classloader. If you find such a problem, you will need to request a fix with the original authors.

20.3 LiveReload

The spring-boot-devtools module includes an embedded LiveReload server that can be used to trigger a browser refresh when a resource is changed. LiveReload browser extensions are freely available for Chrome, Firefox and Safari from <u>livereload.com</u>.

If you don't want to start the LiveReload server when your application runs you can set the spring.devtools.livereload.enabled property to false.

Note

You can only run one LiveReload server at a time, if you start multiple applications from your IDE only the first will have livereload support.

20.4 Global settings

You can configure global devtools settings by adding a file named .spring-bootdevtools.properties to your \$HOME folder (note that the filename starts with "."). Any properties added to this file will apply to *all* Spring Boot applications on your machine that use devtools. For example, to configure restart to always use a <u>trigger file</u>, you would add the following:

~/.spring-boot-devtools.properties.

```
spring.devtools.reload.trigger-file=.reloadtrigger
```

20.5 Remote applications

The Spring Boot developer tools are not just limited to local development. You can also use several features when running applications remotely. Remote support is opt-in, to enable it you need to set a spring.devtools.remote.secret property. For example:

spring.devtools.remote.secret=mysecret

Warning

Enabling spring-boot-devtools on a remote application is a security risk. You should never enable support on a production deployment.

Remote devtools support is provided in two parts; there is a server side endpoint that accepts connections, and a client application that you run in your IDE. The server component is automatically enabled when the spring.devtools.remote.secret property is set. The client component must be launched manually.

Running the remote client application

The remote client application is designed to be run from within you IDE. You need to run org.springframework.boot.devtools.RemoteSpringApplication using the same classpath as the remote project that you're connecting to. The *non-option* argument passed to the application should be the remote URL that you are connecting to.

For example, if you are using Eclipse or STS, and you have a project named m_{y-app} that you've deployed to Cloud Foundry, you would do the following:

- Select Run Configurations... from the Run menu.
- Create a new Java Application "launch configuration".
- Browse for the my-app project.
- Use org.springframework.boot.devtools.RemoteSpringApplication as the main class.
- Add https://myapp.cfapps.io to the Program arguments (or whatever your remote URL is).

A running remote client will look like this:

<pre></pre>		
2015-06-10 18:25:06.632 INFO 14938 [main] o.s.b.devtools.RemoteSpringApplication	:	
Starting RemoteSpringApplication on pwmbp with PID 14938 (/Users/pwebb/projects/spring-boot/code/		
spring-boot-devtools/target/classes started by pwebb in /Users/pwebb/projects/spring-boot/code/spring-		
boot-samples/spring-boot-sample-devtools)		
2015-06-10 18:25:06.671 INFO 14938 [main] s.c.a.AnnotationConfigApplicationContext	:	
Refreshing org.springframework.context.annotation.AnnotationConfigApplicationContext@2a17b7b6: st	artup	
date [Wed Jun 10 18:25:06 PDT 2015]; root of context hierarchy		
2015-06-10 18:25:07.043 WARN 14938 [main] o.s.b.d.r.c.RemoteClientConfiguration	: The	
connection to http://localhost:8080 is insecure. You should use a URL starting with 'https://'.		
2015-06-10 18:25:07.074 INFO 14938 [main] o.s.b.d.a.OptionalLiveReloadServer	:	
LiveReload server is running on port 35729		
2015-06-10 18:25:07.130 INFO 14938 [main] o.s.b.devtools.RemoteSpringApplication	:	
Started RemoteSpringApplication in 0.74 seconds (JVM running for 1.105)		

Note

Because the remote client is using the same classpath as the real application it can directly read application properties. This is how the spring.devtools.remote.secret property is read and passed to the server for authentication.

Тір

It's always advisable to use https:// as the connection protocol so that traffic is encrypted and passwords cannot be intercepted.

Тір

If you need to use a proxy to access the remote application, configure the spring.devtools.remote.proxy.host and spring.devtools.remote.proxy.port properties.

Remote update

The remote client will monitor your application classpath for changes in the same way as the <u>local restart</u>. Any updated resource will be pushed to the remote application and *(if required)* trigger a restart. This can be quite helpful if you are iterating on a feature that uses a cloud service that you don't have locally. Generally remote updates and restarts are much quicker than a full rebuild and deploy cycle.

Note

Files are only monitored when the remote client is running. If you change a file before starting the remote client, it won't be pushed to the remote server.

Remote debug tunnel

Java remote debugging is useful when diagnosing issues on a remote application. Unfortunately, it's not always possible to enable remote debugging when your application is deployed outside of your data center. Remote debugging can also be tricky to setup if you are using a container based technology such as Docker.

To help work around these limitations, devtools supports tunneling of remote debug traffic over HTTP. The remote client provides a local server on port 8000 that you can attach a remote debugger to. Once a connection is established, debug traffic is sent over HTTP to the remote application. You can use the spring.devtools.remote.debug.local-port property if you want to use a different port.

You'll need to ensure that your remote application is started with remote debugging enabled. Often this can be achieved by configuring JAVA_OPTS. For example, with Cloud Foundry you can add the following to your manifest.yml:

-env: JAVA_OPTS: "-Xdebug -Xrunjdwp:server=y,transport=dt_socket,suspend=n"

Тір

Notice that you don't need to pass an address=NNNN option to -Xrunjdwp. If omitted Java will simply pick a random free port.

Note

Debugging a remote service over the Internet can be slow and you might need to increase timeouts in your IDE. For example, in Eclipse you can select $Java \rightarrow Debug$ from Preferences... and change the Debugger timeout (ms) to a more suitable value (60000 works well in most situations).

21. Packaging your application for production

Executable jars can be used for production deployment. As they are self-contained, they are also ideally suited for cloud-based deployment.

For additional "production ready" features, such as health, auditing and metric REST or JMX endpoints; consider adding spring-boot-actuator. See <u>Part V, "Spring Boot Actuator: Production-</u> <u>ready features</u>" for details.

22. What to read next

You should now have good understanding of how you can use Spring Boot along with some best practices that you should follow. You can now go on to learn about specific <u>Spring Boot features</u> in depth, or you could skip ahead and read about the "production ready" aspects of Spring Boot.

Part IV. Spring Boot features

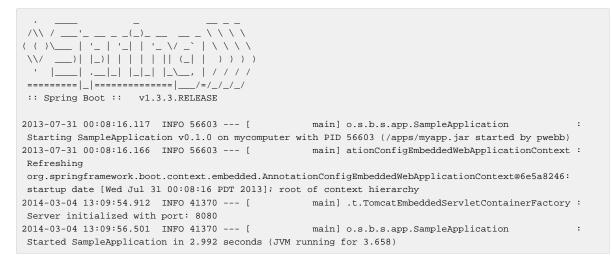

This section dives into the details of Spring Boot. Here you can learn about the key features that you will want to use and customize. If you haven't already, you might want to read the <u>Part II, "Getting started"</u> and <u>Part III, "Using Spring Boot"</u> sections so that you have a good grounding of the basics.

23. SpringApplication

The SpringApplication class provides a convenient way to bootstrap a Spring application that will be started from a main() method. In many situations you can just delegate to the static SpringApplication.run method:

```
public static void main(String[] args) {
    SpringApplication.run(MySpringConfiguration.class, args);
}
```

When your application starts you should see something similar to the following:

By default INFO logging messages will be shown, including some relevant startup details such as the user that launched the application.

23.1 Customizing the Banner

The banner that is printed on start up can be changed by adding a banner.txt file to your classpath, or by setting banner.location to the location of such a file. If the file has an unusual encoding you can set banner.charset (default is UTF-8).

You can use the following variables inside your banner.txt file:

Variable	Description
\${application.version}	The version number of your application as declared in MANIFEST.MF. For example Implementation-Version: 1.0 is printed as 1.0.
\${application.formatted-version}	The version number of your application as declared in MANIFEST.MF formatted for display (surrounded with brackets and prefixed with v). For example (v1.0).
\${spring-boot.version}	The Spring Boot version that you are using. For example 1.3.3.RELEASE.

Table 23.1. Banner variables

Variable	Description
\${spring-boot.formatted-version}	The Spring Boot version that you are using formatted for display (surrounded with brackets and prefixed with v). For example (v1.3.3.RELEASE).
<pre>\${Ansi.NAME} (or \${AnsiColor.NAME}, \${AnsiBackground.NAME}, \${AnsiStyle.NAME})</pre>	Where NAME is the name of an ANSI escape code. See <u>AnsiPropertySource</u> for details.
\${application.title}	The title of your application as declared in MANIFEST.MF. For example Implementation-Title: MyApp is printed as MyApp.

Тір

The SpringApplication.setBanner(...) method can be used if you want to generate a banner programmatically. Use the org.springframework.boot.Banner interface and implement your own printBanner() method.

You can also use the spring.main.banner-mode property to determine if the banner has to be printed on System.out (console), using the configured logger (log) or not at all (off).

Note

YAML maps off to false so make sure to add quotes if you want to disable the banner in your application.

```
spring:
    main:
    banner-mode: "off"
```

23.2 Customizing SpringApplication

If the SpringApplication defaults aren't to your taste you can instead create a local instance and customize it. For example, to turn off the banner you would write:

```
public static void main(String[] args) {
    SpringApplication app = new SpringApplication(MySpringConfiguration.class);
    app.setBannerMode(Banner.Mode.OFF);
    app.run(args);
}
```

Note

The constructor arguments passed to SpringApplication are configuration sources for spring beans. In most cases these will be references to @Configuration classes, but they could also be references to XML configuration or to packages that should be scanned.

It is also possible to configure the SpringApplication using an application.properties file. See <u>Chapter 24, Externalized Configuration</u> for details.

For a complete list of the configuration options, see the <u>SpringApplication Javadoc</u>.

23.3 Fluent builder API

If you need to build an ApplicationContext hierarchy (multiple contexts with a parent/ child relationship), or if you just prefer using a 'fluent' builder API, you can use the SpringApplicationBuilder.

The SpringApplicationBuilder allows you to chain together multiple method calls, and includes parent and child methods that allow you to create a hierarchy.

For example:

```
new SpringApplicationBuilder()
   .bannerMode(Banner.Mode.OFF)
   .sources(Parent.class)
   .child(Application.class)
   .run(args);
```

Note

There are some restrictions when creating an ApplicationContext hierarchy, e.g. Web components **must** be contained within the child context, and the same Environment will be used for both parent and child contexts. See the <u>SpringApplicationBuilder Javadoc</u> for full details.

23.4 Application events and listeners

In addition to the usual Spring Framework events, such as <u>ContextRefreshedEvent</u>, a SpringApplication sends some additional application events.

Note

Some events are actually triggered before the ApplicationContext is created register SO you cannot а listener on those as а @Bean. You can register them via the SpringApplication.addListeners(...) or SpringApplicationBuilder.listeners(...) methods.

If you want those listeners to be registered automatically regardless of the way the application is created you can add a META-INF/spring.factories file to your project and reference your listener(s) using the org.springframework.context.ApplicationListener key.

org.springframework.context.ApplicationListener=com.example.project.MyListener

Application events are sent in the following order, as your application runs:

- 1. An ApplicationStartedEvent is sent at the start of a run, but before any processing except the registration of listeners and initializers.
- 2. An ApplicationEnvironmentPreparedEvent is sent when the Environment to be used in the context is known, but before the context is created.
- 3. An ApplicationPreparedEvent is sent just before the refresh is started, but after bean definitions have been loaded.

- 4. An ApplicationReadyEvent is sent after the refresh and any related callbacks have been processed to indicate the application is ready to service requests.
- 5. An ApplicationFailedEvent is sent if there is an exception on startup.

Tip

You often won't need to use application events, but it can be handy to know that they exist. Internally, Spring Boot uses events to handle a variety of tasks.

23.5 Web environment

A SpringApplication will attempt to create the right type of ApplicationContext on your behalf. By default, an AnnotationConfigApplicationContext or AnnotationConfigEmbeddedWebApplicationContext will be used, depending on whether you are developing a web application or not.

The algorithm used to determine a 'web environment' is fairly simplistic (based on the presence of a few classes). You can use setWebEnvironment(boolean webEnvironment) if you need to override the default.

It is also possible to take complete control of the ApplicationContext type that will be used by calling setApplicationContextClass(...).

Тір

It is often desirable to call setWebEnvironment(false) when using SpringApplication within a JUnit test.

23.6 Accessing application arguments

If you need to access the application arguments that were passed to SpringApplication.run(...) you can inject a org.springframework.boot.ApplicationArguments bean. The ApplicationArguments interface provides access to both the raw String[] arguments as well as parsed option and non-option arguments:

```
import org.springframework.boot.*
import org.springframework.beans.factory.annotation.*
import org.springframework.stereotype.*
@Component
public class MyBean {
    @Autowired
    public MyBean(ApplicationArguments args) {
        boolean debug = args.containsOption("debug");
        List<String> files = args.getNonOptionArgs();
        // if run with "--debug logfile.txt" debug=true, files=["logfile.txt"]
    }
}
```

Тір

Spring Boot will also register a CommandLinePropertySource with the Spring Environment. This allows you to also inject single application arguments using the @Value annotation.

23.7 Using the ApplicationRunner or CommandLineRunner

If you need to run some specific code once the SpringApplication has started, you can implement the ApplicationRunner or CommandLineRunner interfaces. Both interfaces work in the same way and offer a single run method which will be called just before SpringApplication.run(...) completes.

The CommandLineRunner interfaces provides access to application arguments as a simple string array, whereas the ApplicationRunner uses the ApplicationArguments interface discussed above.

```
import org.springframework.boot.*
import org.springframework.stereotype.*
@Component
public class MyBean implements CommandLineRunner {
    public void run(String... args) {
        // Do something...
    }
}
```

You can additionally implement the org.springframework.core.Ordered interface or use the org.springframework.core.annotation.Order annotation if several CommandLineRunner or ApplicationRunner beans are defined that must be called in a specific order.

23.8 Application exit

Each SpringApplication will register a shutdown hook with the JVM to ensure that the ApplicationContext is closed gracefully on exit. All the standard Spring lifecycle callbacks (such as the DisposableBean interface, or the @PreDestroy annotation) can be used.

In addition, beans may implement the org.springframework.boot.ExitCodeGenerator interface if they wish to return a specific exit code when the application ends.

23.9 Admin features

It is possible to enable admin-related features for the application by specifying the spring.application.admin.enabled property. This exposes the SpringApplicationAdminMXBean on the platform MBeanServer. You could use this feature to administer your Spring Boot application remotely. This could also be useful for any service wrapper implementation.

Тір

If you want to know on which HTTP port the application is running, get the property with key local.server.port.

Note

Take care when enabling this feature as the MBean exposes a method to shutdown the application.

24. Externalized Configuration

Spring Boot allows you to externalize your configuration so you can work with the same application code in different environments. You can use properties files, YAML files, environment variables and command-line arguments to externalize configuration. Property values can be injected directly into your beans using the @Value annotation, accessed via Spring's Environment abstraction or <u>bound to</u> <u>structured objects</u> via @ConfigurationProperties.

Spring Boot uses a very particular PropertySource order that is designed to allow sensible overriding of values, properties are considered in the following order:

- 1. Command line arguments.
- 2. Properties from SPRING_APPLICATION_JSON (inline JSON embedded in an environment variable or system property)
- 3. JNDI attributes from java:comp/env.
- 4. Java System properties (System.getProperties()).
- 5. OS environment variables.
- 6. A RandomValuePropertySource that only has properties in random.*.
- 7. <u>Profile-specific application properties</u> outside of your packaged jar (application-{profile}.properties and YAML variants)
- 8. <u>Profile-specific application properties</u> packaged inside your jar (application-{profile}.properties and YAML variants)
- 9. Application properties outside of your packaged jar (application.properties and YAML variants).
- 10 Application properties packaged inside your jar (application.properties and YAML variants).
- 11<u>@PropertySource</u> annotations on your @Configuration classes.

12Default properties (specified using SpringApplication.setDefaultProperties).

To provide a concrete example, suppose you develop a @Component that uses a name property:

```
import org.springframework.stereotype.*
import org.springframework.beans.factory.annotation.*
@Component
public class MyBean {
    @Value("${name}")
    private String name;
    // ...
}
```

On your application classpath (e.g. inside your jar) you can have an application.properties that provides a sensible default property value for name. When running in a new environment, an application.properties can be provided outside of your jar that overrides the name; and for one-off testing, you can launch with a specific command line switch (e.g. java -jar app.jar -- name="Spring").

Тір

The SPRING_APPLICATION_JSON properties can be supplied on the command line with an environment variable. For example in a UN*X shell:

\$ SPRING_APPLICATION_JSON='{"foo":{"bar":"spam"}}' java -jar myapp.jar

In this example you will end up with foo.bar=spam in the Spring Environment. You can also supply the JSON as spring.application.json in a System variable:

\$ java -Dspring.application.json='{"foo":"bar"}' -jar myapp.jar

or command line argument:

```
$ java -jar myapp.jar --spring.application.json='{"foo":"bar"}'
```

or as a JNDI variable java:comp/env/spring.application.json.

24.1 Configuring random values

The RandomValuePropertySource is useful for injecting random values (e.g. into secrets or test cases). It can produce integers, longs or strings, e.g.

```
my.secret=${random.value}
my.number=${random.int}
my.bignumber=${random.long}
my.number.less.than.ten=${random.int(10)}
my.number.in.range=${random.int[1024,65536]}
```

The random.int* syntax is OPEN value (,max) CLOSE where the OPEN, CLOSE are any character and value, max are integers. If max is provided then value is the minimum value and max is the maximum (exclusive).

24.2 Accessing command line properties

By default SpringApplication will convert any command line option arguments (starting with '--', e.g. --server.port=9000) to a property and add it to the Spring Environment. As mentioned above, command line properties always take precedence over other property sources.

If you don't want command line properties to be added to the Environment you can disable them using SpringApplication.setAddCommandLineProperties(false).

24.3 Application property files

SpringApplication will load properties from application.properties files in the following locations and add them to the Spring Environment:

- 1. A /config subdirectory of the current directory.
- 2. The current directory
- 3. A classpath / config package
- 4. The classpath root

The list is ordered by precedence (properties defined in locations higher in the list override those defined in lower locations).

Note

You can also use YAML ('.yml') files as an alternative to '.properties'.

If you don't like application.properties as the configuration file name you can switch to another by specifying a spring.config.name environment property. You can also refer to an explicit location using the spring.config.location environment property (comma-separated list of directory locations, or file paths).

\$ java -jar myproject.jar --spring.config.name=myproject

or

\$ java -jar myproject.jar --spring.config.location=classpath:/default.properties,classpath:/ override.properties

Warning

spring.config.name and spring.config.location are used very early to determine which files have to be loaded so they have to be defined as an environment property (typically OS env, system property or command line argument).

If spring.config.location contains directories (as opposed to files) they should end in / (and will be appended with the names generated from spring.config.name before being loaded, including profile-specific file names). Files specified in spring.config.location are used as-is, with no support for profile-specific variants, and will be overridden by any profile-specific properties.

The default search path classpath:,classpath:/config,file:,file:config/ is always used, irrespective of the value of spring.config.location. This search path is ordered from lowest to highest precedence (file:config/ wins). If you do specify your own locations, they take precedence over all of the default locations and use the same lowest to highest precedence ordering. In that way you can set up default values for your application in application.properties (or whatever other basename you choose with spring.config.name) and override it at runtime with a different file, keeping the defaults.

Note

If you use environment variables rather than system properties, most operating systems disallow period-separated key names, but you can use underscores instead (e.g. SPRING_CONFIG_NAME instead of spring.config.name).

Note

If you are running in a container then JNDI properties (in java:comp/env) or servlet context initialization parameters can be used instead of, or as well as, environment variables or system properties.

24.4 Profile-specific properties

In addition to application.properties files, profile-specific properties can also be defined using the naming convention application-{profile}.properties. The Environment has a set of

default profiles (by default [default]) which are used if no active profiles are set (i.e. if no profiles are explicitly activated then properties from application-default.properties are loaded).

Profile-specific properties are loaded from the same locations as standard application.properties, with profile-specific files always overriding the non-specific ones irrespective of whether the profile-specific files are inside or outside your packaged jar.

If several profiles are specified, a last wins strategy applies. For example, profiles specified by the spring.profiles.active property are added after those configured via the SpringApplication API and therefore take precedence.

Note

If you have specified any files in spring.config.location, profile-specific variants of those files will not be considered. Use directories in `spring.config.location` if you also want to also use profile-specific properties.

24.5 Placeholders in properties

The values in application.properties are filtered through the existing Environment when they are used so you can refer back to previously defined values (e.g. from System properties).

```
app.name=MyApp
app.description=${app.name} is a Spring Boot application
```

Тір

You can also use this technique to create 'short' variants of existing Spring Boot properties. See the <u>Section 69.3, "Use 'short' command line arguments</u>" how-to for details.

24.6 Using YAML instead of Properties

<u>YAML</u> is a superset of JSON, and as such is a very convenient format for specifying hierarchical configuration data. The SpringApplication class will automatically support YAML as an alternative to properties whenever you have the <u>SnakeYAML</u> library on your classpath.

Note

If you use 'starter POMs' SnakeYAML will be automatically provided via spring-boot-starter.

Loading YAML

Spring Framework provides two convenient classes that can be used to load YAML documents. The YamlPropertiesFactoryBean will load YAML as Properties and the YamlMapFactoryBean will load YAML as a Map.

For example, the following YAML document:

```
environments:
dev:
url: http://dev.bar.com
name: Developer Setup
```

prod: url: http://foo.bar.com name: My Cool App

Would be transformed into these properties:

```
environments.dev.url=http://dev.bar.com
environments.dev.name=Developer Setup
environments.prod.url=http://foo.bar.com
environments.prod.name=My Cool App
```

YAML lists are represented as property keys with [index] dereferencers, for example this YAML:

```
my:
servers:
- dev.bar.com
- foo.bar.com
```

Would be transformed into these properties:

```
my.servers[0]=dev.bar.com
my.servers[1]=foo.bar.com
```

To bind to properties like that using the Spring DataBinder utilities (which is what @ConfigurationProperties does) you need to have a property in the target bean of type java.util.List (or Set) and you either need to provide a setter, or initialize it with a mutable value, e.g. this will bind to the properties above

```
@ConfigurationProperties(prefix="my")
public class Config {
    private List<String> servers = new ArrayList<String>();
    public List<String> getServers() {
        return this.servers;
    }
}
```

Exposing YAML as properties in the Spring Environment

The YamlPropertySourceLoader class can be used to expose YAML as a PropertySource in the Spring Environment. This allows you to use the familiar @Value annotation with placeholders syntax to access YAML properties.

Multi-profile YAML documents

You can specify multiple profile-specific YAML documents in a single file by using a spring.profiles key to indicate when the document applies. For example:

```
server:
    address: 192.168.1.100
----
spring:
    profiles: development
server:
    address: 127.0.0.1
----
spring:
    profiles: production
server:
    address: 192.168.1.120
```

In the example above, the server.address property will be 127.0.0.1 if the development profile is active. If the development and production profiles are **not** enabled, then the value for the property will be 192.168.1.100.

The default profiles are activated if none are explicitly active when the application context starts. So in this YAML we set a value for security.user.password that is **only** available in the "default" profile:

whereas in this example, the password is always set because it isn't attached to any profile, and it would have to be explicitly reset in all other profiles as necessary:

```
server:
   port: 8000
security:
   user:
   password: weak
```

YAML shortcomings

YAML files can't be loaded via the @PropertySource annotation. So in the case that you need to load values that way, you need to use a properties file.

24.7 Type-safe Configuration Properties

Using the <code>@Value("\${property}")</code> annotation to inject configuration properties can sometimes be cumbersome, especially if you are working with multiple properties or your data is hierarchical in nature. Spring Boot provides an alternative method of working with properties that allows strongly typed beans to govern and validate the configuration of your application. For example:

```
@Component
@ConfigurationProperties(prefix="connection")
public class ConnectionSettings {
    private String username;
    private InetAddress remoteAddress;
    // ... getters and setters
}
```

Note

The getters and setters are advisable, since binding is via standard Java Beans property descriptors, just like in Spring MVC. They are mandatory for immutable types or those that are directly coercible from String. As long as they are initialized, maps, collections, and arrays need a getter but not necessarily a setter since they can be mutated by the binder. If there is a setter, Maps, collections, and arrays can be created. Maps and collections can be expanded with only a getter, whereas arrays require a setter. Nested POJO properties can also be created (so a setter is not mandatory) if they have a default constructor, or a constructor accepting a single value

that can be coerced from String. Some people use Project Lombok to add getters and setters automatically.

Note

Contrary to @Value, SpEL expressions are not evaluated prior to injecting a value in the relevant @ConfigurationProperties bean.

The <code>@EnableConfigurationProperties</code> annotation is automatically applied to your project so that any beans annotated with <code>@ConfigurationProperties</code> will be configured from the <code>Environment</code> properties. This style of configuration works particularly well with the <code>SpringApplication</code> external YAML configuration:

```
# application.yml
connection:
    username: admin
    remoteAddress: 192.168.1.1
# additional configuration as required
```

To work with @ConfigurationProperties beans you can just inject them in the same way as any other bean.

```
@Service
public class MyService {
    @Autowired
    private ConnectionSettings connection;
    //...
    @PostConstruct
    public void openConnection() {
        Server server = new Server();
        this.connection.configure(server);
    }
}
```

It is also possible to shortcut the registration of @ConfigurationProperties bean definitions by simply listing the properties classes directly in the @EnableConfigurationProperties annotation:

```
@Configuration
@EnableConfigurationProperties(ConnectionSettings.class)
public class MyConfiguration {
}
```

Тір

Using @ConfigurationProperties also allows you to generate meta-data files that can be used by IDEs. See the <u>Appendix B</u>, <u>Configuration meta-data</u> appendix for details.

Third-party configuration

As well as using @ConfigurationProperties to annotate a class, you can also use it on @Bean methods. This can be particularly useful when you want to bind properties to third-party components that are outside of your control.

To configure a bean from the Environment properties, add @ConfigurationProperties to its bean registration:

```
@ConfigurationProperties(prefix = "foo")
@Bean
public FooComponent fooComponent() {
    ...
}
```

Any property defined with the foo prefix will be mapped onto that FooComponent bean in a similar manner as the ConnectionSettings example above.

Relaxed binding

Spring Boot uses some relaxed rules for binding Environment properties to @ConfigurationProperties beans, so there doesn't need to be an exact match between the Environment property name and the bean property name. Common examples where this is useful include dashed separated (e.g. context-path binds to contextPath), and capitalized (e.g. PORT binds to port) environment properties.

For example, given the following @ConfigurationProperties class:

```
@Component
@ConfigurationProperties(prefix="person")
public class ConnectionSettings {
    private String firstName;
    public String getFirstName() {
        return this.firstName;
    }
    public void setFirstName(String firstName) {
        this.firstName = firstName;
    }
}
```

The following properties names can all be used:

Table 24.1. relaxed binding

Property	Note			
person.firstNam Standard camel case syntax .				
person.first- name	Dashed notation, recommended for use in .properties and .yml files.			
PERSON_FIRST_N	Ablipper case format. Recommended when using a system environment variables.			

Properties conversion

Spring will attempt to coerce the external application properties to the right type when it binds to the @ConfigurationProperties beans. If you need custom type conversion you can provide a ConversionService bean (with bean id conversionService) or custom property editors (via a CustomEditorConfigurer bean) or custom Converters (with bean definitions annotated as @ConfigurationPropertiesBinding).

Note

As this bean is requested very early during the application lifecycle, make sure to limit the dependencies that your ConversionService is using. Typically, any dependency that you require may not be fully initialized at creation time. You may want to rename your custom ConversionService if it's not required for configuration keys coercion and only rely on custom converters qualified with @ConfigurationPropertiesBinding.

@ConfigurationProperties Validation

Spring Boot will attempt to validate external configuration, by default using JSR-303 (if it is on the classpath). You can simply add JSR-303 javax.validation constraint annotations to your @ConfigurationProperties class:

```
@Component
@ConfigurationProperties(prefix="connection")
public class ConnectionSettings {
    @NotNull
    private InetAddress remoteAddress;
    // ... getters and setters
}
```

In order to validate values of nested properties, you must annotate the associated field as @Valid to trigger its validation. For example, building upon the above ConnectionSettings example:

```
@Component
@ConfigurationProperties(prefix="connection")
public class ConnectionSettings {
    @NotNull
    @Valid
    private RemoteAddress remoteAddress;
    // ... getters and setters
    public static class RemoteAddress {
        @NotEmpty
        public String hostname;
        // ... getters and setters
    }
}
```

You can also add a custom Spring Validator by creating a bean definition called configurationPropertiesValidator. There is a <u>Validation sample</u> so you can see how to set things up.

Тір

The spring-boot-actuator module includes an endpoint that exposes all @ConfigurationProperties beans. Simply point your web browser to /configprops or use the equivalent JMX endpoint. See the <u>Production ready features</u>. section for details.

25. Profiles

Spring Profiles provide a way to segregate parts of your application configuration and make it only available in certain environments. Any @Component or @Configuration can be marked with @Profile to limit when it is loaded:

```
@Configuration
@Profile("production")
public class ProductionConfiguration {
    // ...
}
```

In the normal Spring way, you can use a spring.profiles.active Environment property to specify which profiles are active. You can specify the property in any of the usual ways, for example you could include it in your application.properties:

spring.profiles.active=dev,hsqldb

or specify on the command line using the switch --spring.profiles.active=dev,hsqldb.

25.1 Adding active profiles

The spring.profiles.active property follows the same ordering rules as other properties, the highest PropertySource will win. This means that you can specify active profiles in application.properties then **replace** them using the command line switch.

Sometimes it is useful to have profile-specific properties that **add** to the active profiles rather than replace them. The spring.profiles.include property can be used to unconditionally add active profiles. The SpringApplication entry point also has a Java API for setting additional profiles (i.e. on top of those activated by the spring.profiles.active property): see the setAdditionalProfiles() method.

For example, when an application with following properties is run using the switch -- spring.profiles.active=prod the proddb and prodmq profiles will also be activated:

```
my.property: fromyamlfile
---
spring.profiles: prod
spring.profiles.include: proddb,prodmq
```

Note

Remember that the spring.profiles property can be defined in a YAML document to determine when this particular document is included in the configuration. See <u>Section 69.6</u>, <u>"Change configuration depending on the environment"</u> for more details.

25.2 Programmatically setting profiles

You can programmatically set active profiles by calling SpringApplication.setAdditionalProfiles(...) before your application runs. It is also possible to activate profiles using Spring's ConfigurableEnvironment interface.

25.3 Profile-specific configuration files

Profile-specific variants of both application.properties (or application.yml) and files referenced via @ConfigurationProperties are considered as files are loaded. See <u>Section 24.4</u>, <u>"Profile-specific properties</u>" for details.

26. Logging

Spring Boot uses <u>Commons Logging</u> for all internal logging, but leaves the underlying log implementation open. Default configurations are provided for <u>Java Util Logging</u>, <u>Log4J</u>, <u>Log4J2</u> and <u>Logback</u>. In each case loggers are pre-configured to use console output with optional file output also available.

By default, If you use the 'Starter POMs', Logback will be used for logging. Appropriate Logback routing is also included to ensure that dependent libraries that use Java Util Logging, Commons Logging, Log4J or SLF4J will all work correctly.

Тір

There are a lot of logging frameworks available for Java. Don't worry if the above list seems confusing. Generally you won't need to change your logging dependencies and the Spring Boot defaults will work just fine.

26.1 Log format

The default log output from Spring Boot looks like this:

```
2014-03-05 10:57:51.112 INFO 45469 --- [ main] org.apache.catalina.core.StandardEngine :
Starting Servlet Engine: Apache Tomcat/7.0.52
2014-03-05 10:57:51.253 INFO 45469 --- [ost-startStop-1] o.a.c.c.C.[Tomcat].[localhost].[/] :
Initializing Spring embedded WebApplicationContext
2014-03-05 10:57:51.253 INFO 45469 --- [ost-startStop-1] o.s.web.context.ContextLoader :
Root WebApplicationContext: initialization completed in 1358 ms
2014-03-05 10:57:51.698 INFO 45469 --- [ost-startStop-1] o.s.b.c.e.ServletRegistrationBean :
Mapping servlet: 'dispatcherServlet' to [/]
2014-03-05 10:57:51.702 INFO 45469 --- [ost-startStop-1] o.s.b.c.embedded.FilterRegistrationBean :
Mapping filter: 'hiddenHttpMethodFilter' to: [/*]
```

The following items are output:

- Date and Time Millisecond precision and easily sortable.
- Log Level ERROR, WARN, INFO, DEBUG or TRACE.
- Process ID.
- A --- separator to distinguish the start of actual log messages.
- Thread name Enclosed in square brackets (may be truncated for console output).
- Logger name This is usually the source class name (often abbreviated).
- The log message.

Note

Logback does not have a FATAL level (it is mapped to ERROR)

26.2 Console output

The default log configuration will echo messages to the console as they are written. By default ERROR, WARN and INFO level messages are logged. You can also enable a "debug" mode by starting your application with a --debug flag.

\$ java -jar myapp.jar --debug

Note

you can also specify debug=true in your application.properties.

When the debug mode is enabled, a selection of core loggers (embedded container, Hibernate and Spring) are configured to output more information. Enabling the debug mode does *not* configure your application log all messages with DEBUG level.

Color-coded output

If your terminal supports ANSI, color output will be used to aid readability. You can set spring.output.ansi.enabled to a supported value to override the auto detection.

Color coding is configured using the %clr conversion word. In its simplest form the converter will color the output according to the log level, for example:

%clr(%5p)

The mapping of log level to a color is as follows:

Level	Color
FATAL	Red
ERROR	Red
WARN	Yellow
INFO	Green
DEBUG	Green
TRACE	Green

Alternatively, you can specify the color or style that should be used by providing it as an option to the conversion. For example, to make the text yellow:

%clr(%d{yyyy-MM-dd HH:mm:ss.SSS}){yellow}

The following colors and styles are supported:

- blue
- cyan
- faint
- green
- magenta
- red

• yellow

26.3 File output

By default, Spring Boot will only log to the console and will not write log files. If you want to write log files in addition to the console output you need to set a logging.file or logging.path property (for example in your application.properties).

The following table shows how the logging. * properties can be used together:

Table 26.1. Logging properties

logging.fi	llægging.pa	uExample	Description
(none)	(none)		Console only logging.
Specific file	(none)	my.log	Writes to the specified log file. Names can be an exact location or relative to the current directory.
(none)	Specific directory	/var/log	Writes spring.log to the specified directory. Names can be an exact location or relative to the current directory.

Log files will rotate when they reach 10 Mb and as with console output, ERROR, WARN and INFO level messages are logged by default.

Note

The logging system is initialized early in the application lifecycle and as such logging properties will not be found in property files loaded via <code>@PropertySource</code> annotations.

Тір

Logging properties are independent of the actual logging infrastructure. As a result, specific configuration keys (such as logback.configurationFile for Logback) are not managed by spring Boot.

26.4 Log Levels

All the supported logging systems can have the logger levels set in the Spring Environment (so for example in application.properties) using 'logging.level.*=LEVEL' where 'LEVEL' is one of TRACE, DEBUG, INFO, WARN, ERROR, FATAL, OFF. The root logger can be configured using logging.level.root. Example application.properties:

```
logging.level.root=WARN
logging.level.org.springframework.web=DEBUG
logging.level.org.hibernate=ERROR
```

Note

By default Spring Boot remaps Thymeleaf INFO messages so that they are logged at DEBUG level. This helps to reduce noise in the standard log output. See <u>LevelRemappingAppender</u> for details of how you can apply remapping in your own configuration.

26.5 Custom log configuration

The various logging systems can be activated by including the appropriate libraries on the classpath, and further customized by providing a suitable configuration file in the root of the classpath, or in a location specified by the Spring Environment property logging.config.

Note

Since logging is initialized **before** the ApplicationContext is created, it isn't possible to control logging from @PropertySources in Spring @Configuration files. System properties and the conventional Spring Boot external configuration files work just fine.)

Depending on your logging system, the following files will be loaded:

Logging System	Customization
Logback	<pre>logback-spring.xml, logback- spring.groovy, logback.xml OF logback.groovy</pre>
Log4j	<pre>log4j-spring.properties, log4j- spring.xml, log4j.properties or log4j.xml</pre>
Log4j2	log4j2-spring.xml or log4j2.xml
JDK (Java Util Logging)	logging.properties

Note

When possible we recommend that you use the *-spring* variants for your logging configuration (for example logback-spring.xml rather than logback.xml). If you use standard configuration locations, Spring cannot completely control log initialization.

Warning

There are known classloading issues with Java Util Logging that cause problems when running from an 'executable jar'. We recommend that you avoid it if at all possible.

To help with the customization some other properties are transferred from the Spring Environment to System properties:

Spring Environment	System Property	Comments
logging.exception- conversion-word	LOG_EXCEPTION_CONVERSION	₩beconversion word that's used when logging exceptions.
logging.file	LOG_FILE	Used in default log configuration if defined.
logging.path	LOG_PATH	Used in default log configuration if defined.

Spring Environment	System Property	Comments
logging.pattern.console	CONSOLE_LOG_PATTERN	The log pattern to use on the console (stdout). (Not supported with JDK logger.)
logging.pattern.file	FILE_LOG_PATTERN	The log pattern to use in a file (if LOG_FILE enabled). (Not supported with JDK logger.)
logging.pattern.level	LOG_LEVEL_PATTERN	The format to use to render the log level (default %5p). (The logging.pattern.level form is only supported by Logback.)
PID	PID	The current process ID (discovered if possible and when not already defined as an OS environment variable).

All the logging systems supported can consult System properties when parsing their configuration files. See the default configurations in spring-boot.jar for examples.

Тір

If you want to use a placeholder in a logging property, you should use <u>Spring Boot's syntax</u> and not the syntax of the underlying framework. Notably, if you're using Logback, you should use : as the delimiter between a property name and its default value and not :-.

Тір

You can add MDC and other ad-hoc content to log lines by overriding only the LOG_LEVEL_PATTERN (or logging.pattern.level with Logback). For example, if you use logging.pattern.level=user:%X{user} %5p then the default log format will contain an MDC entry for "user" if it exists, e.g.

```
2015-09-30 12:30:04.031 user:juergen INFO 22174 --- [ nio-8080-exec-0] demo.Controller Handling authenticated request
```

26.6 Logback extensions

Spring Boot includes a number of extensions to Logback which can help with advanced configuration. You can use these extensions in your logback-spring.xml configuration file.

Note

You cannot use extensions in the standard logback.xml configuration file since it's loaded too early. You need to either use logback-spring.xml or define a logging.config property.

Profile-specific configuration

The <springProfile> tag allows you to optionally include or exclude sections of configuration based on the active Spring profiles. Profile sections are supported anywhere within the <configuration> element. Use the name attribute to specify which profile accepts the configuration. Multiple profiles can be specified using a comma-separated list.

```
<springProfile name="staging">
    <!-- configuration to be enabled when the "staging" profile is active --->
</springProfile>
<springProfile name="dev, staging">
    <!-- configuration to be enabled when the "dev" or "staging" profiles are active --->
</springProfile>
<springProfile name="!production">
    <!-- configuration to be enabled when the "production" profile is not active --->
</springProfile>
```

Environment properties

The <springProperty> tag allows you to surface properties from the Spring Environment for use within Logback. This can be useful if you want to access values from your application.properties file in your logback configuration. The tag works in a similar way to Logback's standard <property> tag, but rather than specifying a direct value you specify the source of the property (from the Environment). You can use the scope attribute if you need to store the property somewhere other than in local scope.

Тір

The RelaxedPropertyResolver is used to access Environment properties. If specify the source in dashed notation (my-property-name) all the relaxed variations will be tried (myPropertyName, MY_PROPERTY_NAME etc).

27. Developing web applications

Spring Boot is well suited for web application development. You can easily create a self-contained HTTP server using embedded Tomcat, Jetty, or Undertow. Most web applications will use the spring-boot-starter-web module to get up and running quickly.

If you haven't yet developed a Spring Boot web application you can follow the "Hello World!" example in the <u>Getting started</u> section.

27.1 The 'Spring Web MVC framework'

The Spring Web MVC framework (often referred to as simply 'Spring MVC') is a rich 'model view controller' web framework. Spring MVC lets you create special @Controller or @RestController beans to handle incoming HTTP requests. Methods in your controller are mapped to HTTP using @RequestMapping annotations.

Here is a typical example @RestController to serve JSON data:

```
@RestController
@RequestMapping(value="/users")
public class MyRestController {
    @RequestMapping(value="/{user}", method=RequestMethod.GET)
    public User getUser(@PathVariable Long user) {
        // ...
    }
    @RequestMapping(value="/{user}/customers", method=RequestMethod.GET)
    List<Customer> getUserCustomers(@PathVariable Long user) {
        // ...
    }
    @RequestMapping(value="/{user}", method=RequestMethod.DELETE)
    public User deleteUser(@PathVariable Long user) {
        // ...
    }
}
```

Spring MVC is part of the core Spring Framework and detailed information is available in the <u>reference</u> <u>documentation</u>. There are also several guides available at <u>spring.io/guides</u> that cover Spring MVC.

Spring MVC auto-configuration

Spring Boot provides auto-configuration for Spring MVC that works well with most applications.

The auto-configuration adds the following features on top of Spring's defaults:

- Inclusion of ContentNegotiatingViewResolver and BeanNameViewResolver beans.
- Support for serving static resources, including support for WebJars (see below).
- Automatic registration of Converter, GenericConverter, Formatter beans.
- Support for HttpMessageConverters (see below).
- Automatic registration of MessageCodesResolver (see below).
- Static index.html support.

- Custom Favicon support.
- Automatic use of a ConfigurableWebBindingInitializer bean (see below).

If you want to take complete control of Spring MVC, you can add your own @Configuration annotated with @EnableWebMvc. If you want to keep Spring Boot MVC features, and you just want to add additional <u>MVC configuration</u> (interceptors, formatters, view controllers etc.) you can add your own @Bean of type WebMvcConfigurerAdapter, but without @EnableWebMvc.

HttpMessageConverters

Spring MVC uses the HttpMessageConverter interface to convert HTTP requests and responses. Sensible defaults are included out of the box, for example Objects can be automatically converted to JSON (using the Jackson library) or XML (using the Jackson XML extension if available, else using JAXB). Strings are encoded using UTF-8 by default.

If you need to add or customize converters you can use Spring Boot's HttpMessageConverters class:

```
import org.springframework.boot.autoconfigure.web.HttpMessageConverters;
import org.springframework.context.annotation.*;
import org.springframework.http.converter.*;
@Configuration
public class MyConfiguration {
    @Bean
    public HttpMessageConverters customConverters() {
        HttpMessageConverter<?> additional = ...
        HttpMessageConverter<?> another = ...
        return new HttpMessageConverters(additional, another);
    }
}
```

Any HttpMessageConverter bean that is present in the context will be added to the list of converters. You can also override default converters that way.

MessageCodesResolver

Spring MVC has a strategy for generating error codes for rendering error messages from binding errors: MessageCodesResolver. Spring Boot will create one for you if you set the spring.mvc.messagecodes-resolver.format property PREFIX_ERROR_CODE or POSTFIX_ERROR_CODE (see the enumeration in DefaultMessageCodesResolver.Format).

Static Content

By default Spring Boot will serve static content from a directory called /static (or /public or / resources or /META-INF/resources) in the classpath or from the root of the ServletContext. It uses the ResourceHttpRequestHandler from Spring MVC so you can modify that behavior by adding your own WebMvcConfigurerAdapter and overriding the addResourceHandlers method.

In a stand-alone web application the default servlet from the container is also enabled, and acts as a fallback, serving content from the root of the ServletContext if Spring decides not to handle it. Most of the time this will not happen (unless you modify the default MVC configuration) because Spring will always be able to handle requests through the DispatcherServlet.

You can customize the static resource locations using spring.resources.staticLocations (replacing the default values with a list of directory locations). If you do this the default welcome page detection will switch to your custom locations, so if there is an index.html in any of your locations on startup, it will be the home page of the application.

In addition to the 'standard' static resource locations above, a special case is made for <u>Webjars content</u>. Any resources with a path in /webjars/** will be served from jar files if they are packaged in the Webjars format.

Тір

Do not use the src/main/webapp directory if your application will be packaged as a jar. Although this directory is a common standard, it will **only** work with war packaging and it will be silently ignored by most build tools if you generate a jar.

Spring Boot also supports advanced resource handling features provided by Spring MVC, allowing use cases such as cache busting static resources or using version agnostic URLs for Webjars.

For example, the following configuration will configure a cache busting solution for all static resources, effectively adding a content hash in URLs, such as link href="/css/spring-2a2d595e6ed9a0b24f027f2b63b134d6.css"/>:

```
spring.resources.chain.strategy.content.enabled=true
spring.resources.chain.strategy.content.paths=/**
```

Note

Links to resources are rewritten at runtime in template, thanks to a ResourceUrlEncodingFilter, auto-configured for Thymeleaf and Velocity. You should manually declare this filter when using JSPs. Other template engines aren't automatically supported right now, but can be with custom template macros/helpers and the use of the ResourceUrlProvider.

When loading resources dynamically with, for example, a JavaScript module loader, renaming files is not an option. That's why other strategies are also supported and can be combined. A "fixed" strategy will add a static version string in the URL, without changing the file name:

```
spring.resources.chain.strategy.content.enabled=true
spring.resources.chain.strategy.content.paths=/**
spring.resources.chain.strategy.fixed.enabled=true
spring.resources.chain.strategy.fixed.paths=/js/lib/
spring.resources.chain.strategy.fixed.version=v12
```

With this configuration, JavaScript modules located under "/js/lib/" will use a fixed versioning strategy "/v12/js/lib/mymodule.js" while other resources will still use the content one <link href="/css/spring-2a2d595e6ed9a0b24f027f2b63b134d6.css"/>.

See <u>ResourceProperties</u> for more of the supported options.

Тір

This feature has been thoroughly described in a dedicated <u>blog post</u> and in Spring Framework's <u>reference documentation</u>.

ConfigurableWebBindingInitializer

Spring MVC uses a WebBindingInitializer to initialize a WebDataBinder for a particular request. If you create your own ConfigurableWebBindingInitializer @Bean, Spring Boot will automatically configure Spring MVC to use it.

Template engines

As well as REST web services, you can also use Spring MVC to serve dynamic HTML content. Spring MVC supports a variety of templating technologies including Velocity, FreeMarker and JSPs. Many other templating engines also ship their own Spring MVC integrations.

Spring Boot includes auto-configuration support for the following templating engines:

- FreeMarker
- <u>Groovy</u>
- <u>Thymeleaf</u>
- <u>Velocity</u>
- <u>Mustache</u>

Тір

JSPs should be avoided if possible, there are several <u>known limitations</u> when using them with embedded servlet containers.

When you're using one of these templating engines with the default configuration, your templates will be picked up automatically from src/main/resources/templates.

Тір

IntelliJ IDEA orders the classpath differently depending on how you run your application. Running your application in the IDE via its main method will result in a different ordering to when you run your application using Maven or Gradle or from its packaged jar. This can cause Spring Boot to fail to find the templates on the classpath. If you're affected by this problem you can reorder the classpath in the IDE to place the module's classes and resources first. Alternatively, you can configure the template prefix to search every templates directory on the classpath: classpath*:/templates/.

Error Handling

Spring Boot provides an /error mapping by default that handles all errors in a sensible way, and it is registered as a 'global' error page in the servlet container. For machine clients it will produce a JSON response with details of the error, the HTTP status and the exception message. For browser clients there is a 'whitelabel' error view that renders the same data in HTML format (to customize it just add a View that resolves to 'error'). To replace the default behaviour completely you can implement ErrorController and register a bean definition of that type, or simply add a bean of type ErrorAttributes to use the existing mechanism but replace the contents.

Тір

The BasicErrorController can be used as a base class for a custom ErrorController. This is particularly useful if you want to add a handler for a new content type (the default is to handle text/html specifically and provide a fallback for everything else). To do that just extend BasicErrorController and add a public method with a @RequestMapping that has a produces attribute, and create a bean of your new type.

You can also define a @ControllerAdvice to customize the JSON document to return for a particular controller and/or exception type.

```
@ControllerAdvice(basePackageClasses = FooController.class)
public class FooControllerAdvice extends ResponseEntityExceptionHandler {
    @ExceptionHandler(YourException.class)
    @ResponseEndity<?> handleControllerException(HttpServletRequest request, Throwable ex) {
        HttpStatus status = getStatus(request);
        return new ResponseEntity<>(new CustomErrorType(status.value(), ex.getMessage()), status);
    }
    private HttpStatus getStatus(HttpServletRequest request) {
        Integer statusCode = (Integer) request.getAttribute("javax.servlet.error.status_code");
        if (statusCode == null) {
            return HttpStatus.INTERNAL_SERVER_ERROR;
        }
        return HttpStatus.valueOf(statusCode);
    }
}
```

In the example above, if YourException is thrown by a controller defined in the same package as FooController, a json representation of the CustomerErrorType POJO will be used instead of the ErrorAttributes representation.

If you want more specific error pages for some conditions, the embedded servlet containers support a uniform Java DSL for customizing the error handling. Assuming that you have a mapping for /400:

```
@Bean
public EmbeddedServletContainerCustomizer containerCustomizer(){
    return new MyCustomizer();
}
/// ...
private static class MyCustomizer implements EmbeddedServletContainerCustomizer {
    @Override
    public void customize(ConfigurableEmbeddedServletContainer container) {
        container.addErrorPages(new ErrorPage(HttpStatus.BAD_REQUEST, "/400"));
    }
}
```

You can also use regular Spring MVC features like <u>@ExceptionHandler methods</u> and <u>@ControllerAdvice</u>. The ErrorController will then pick up any unhandled exceptions.

N.B. if you register an ErrorPage with a path that will end up being handled by a Filter (e.g. as is common with some non-Spring web frameworks, like Jersey and Wicket), then the Filter has to be explicitly registered as an ERROR dispatcher, e.g.

```
@Bean
public FilterRegistrationBean myFilter() {
```

```
FilterRegistrationBean registration = new FilterRegistrationBean();
registration.setFilter(new MyFilter());
...
registration.setDispatcherTypes(EnumSet.allOf(DispatcherType.class));
return registration;
}
```

(the default FilterRegistrationBean does not include the ERROR dispatcher type).

Error Handling on WebSphere Application Server

When deployed to a servlet container, a Spring Boot uses its error page filter to forward a request with an error status to the appropriate error page. The request can only be forwarded to the correct error page if the response has not already been committed. By default, WebSphere Application Server 8.0 and later commits the response upon successful completion of a servlet's service method. You should disable this behaviour by setting com.ibm.ws.webcontainer.invokeFlushAfterService to false

Spring HATEOAS

If you're developing a RESTful API that makes use of hypermedia, Spring Boot provides autoconfiguration for Spring HATEOAS that works well with most applications. The auto-configuration replaces the need to use <code>@EnableHypermediaSupport</code> and registers a number of beans to ease building hypermedia-based applications including a LinkDiscoverers (for client side support) and an ObjectMapper configured to correctly marshal responses into the desired representation. The ObjectMapper will be customized based on the spring.jackson.* properties or a Jackson2ObjectMapperBuilder bean if one exists.

You can take control of Spring HATEOAS's configuration by using @EnableHypermediaSupport. Note that this will disable the ObjectMapper customization described above.

CORS support

<u>Cross-origin resource sharing</u> (CORS) is a <u>W3C specification</u> implemented by <u>most browsers</u> that allows you to specify in a flexible way what kind of cross domain requests are authorized, instead of using some less secure and less powerful approaches like IFRAME or JSONP.

As of version 4.2, Spring MVC <u>supports CORS</u> out of the box. Using <u>controller method CORS</u> <u>configuration</u> with <u>@CrossOrigin</u> annotations in your Spring Boot application does not require any specific configuration. <u>Global CORS configuration</u> can be defined by registering a WebMvcConfigurer bean with a customized addCorsMappings(CorsRegistry) method:

```
@Configuration
public class MyConfiguration {
    @Bean
    public WebMvcConfigurer corsConfigurer() {
        return new WebMvcConfigurerAdapter() {
            @Override
            public void addCorsMappings(CorsRegistry registry) {
                registry.addMapping("/api/**");
            }
        };
    };
}
```

27.2 JAX-RS and Jersey

If you prefer the JAX-RS programming model for REST endpoints you can use one of the available implementations instead of Spring MVC. Jersey 1.x and Apache CXF work quite well out of the box

if you just register their Servlet or Filter as a @Bean in your application context. Jersey 2.x has some native Spring support so we also provide auto-configuration support for it in Spring Boot together with a starter.

To get started with Jersey 2.x just include the spring-boot-starter-jersey as a dependency and then you need one @Bean of type ResourceConfig in which you register all the endpoints:

```
@Component
public class JerseyConfig extends ResourceConfig {
    public JerseyConfig() {
        register(Endpoint.class);
    }
}
```

All the registered endpoints should be @Components with HTTP resource annotations (@GET etc.), e.g.

```
@Component
@Path("/hello")
public class Endpoint {
    @GET
    public String message() {
        return "Hello";
    }
}
```

Since the Endpoint is a Spring @Component its lifecycle is managed by Spring and you can @Autowired dependencies and inject external configuration with @Value. The Jersey servlet will be registered and mapped to /* by default. You can change the mapping by adding @ApplicationPath to your ResourceConfig.

By default Jersey will be set up as a Servlet in a @Bean of type ServletRegistrationBean named jerseyServletRegistration. You can disable or override that bean by creating one of your own with the same name. You can also use a Filter instead of a Servlet by setting spring.jersey.type=filter (in which case the @Bean to replace or override is jerseyFilterRegistration). The servlet has an @Order which you can set with spring.jersey.filter.order. Both the Servlet and the Filter registrations can be given init parameters using spring.jersey.init.* to specify a map of properties.

There is a <u>Jersey sample</u> so you can see how to set things up. There is also a <u>Jersey 1.x sample</u>. Note that in the Jersey 1.x sample that the spring-boot maven plugin has been configured to unpack some Jersey jars so they can be scanned by the JAX-RS implementation (because the sample asks for them to be scanned in its Filter registration). You may need to do the same if any of your JAX-RS resources are packaged as nested jars.

27.3 Embedded servlet container support

Spring Boot includes support for embedded Tomcat, Jetty, and Undertow servers. Most developers will simply use the appropriate 'Starter POM' to obtain a fully configured instance. By default the embedded server will listen for HTTP requests on port 8080.

Servlets, Filters, and listeners

When using an embedded servlet container you can register Servlets, Filters and all the listeners from the Servlet spec (e.g. HttpSessionListener) either by using Spring beans or by scanning for Servlet components.

Registering Servlets, Filters, and listeners as Spring beans

Any Servlet, Filter or Servlet *Listener instance that is a Spring bean will be registered with the embedded container. This can be particularly convenient if you want to refer to a value from your application.properties during configuration.

By default, if the context contains only a single Servlet it will be mapped to /. In the case of multiple Servlet beans the bean name will be used as a path prefix. Filters will map to /*.

If convention-based mapping is not flexible enough you can use the ServletRegistrationBean, FilterRegistrationBean and ServletListenerRegistrationBean classes for complete control.

Servlet Context Initialization

Embedded servlet Servlet containers will not directly execute the 3.0+ javax.servlet.ServletContainerInitializer interface, or Spring's org.springframework.web.WebApplicationInitializer interface. This is an intentional design decision intended to reduce the risk that 3rd party libraries designed to run inside a war will break Spring Boot applications.

lf need perform servlet context initialization you to in а Spring Boot application, you should register а bean that implements the org.springframework.boot.context.embedded.ServletContextInitializer interface. The single onStartup method provides access to the ServletContext, and can easily be used as an adapter to an existing WebApplicationInitializer if necessary.

Scanning for Servlets, Filters, and listeners

When using an embedded container, automatic registration of @WebServlet, @WebFilter, and @WebListener annotated classes can be enabled using @ServletComponentScan.

Тір

@ServletComponentScan will have no effect in a standalone container, where the container's built-in discovery mechanisms will be used instead.

The EmbeddedWebApplicationContext

Under the hood Spring Boot uses a new type of ApplicationContext for embedded servlet container support. The EmbeddedWebApplicationContext is a special type of WebApplicationContext that bootstraps itself by searching for a single EmbeddedServletContainerFactory bean. Usually a TomcatEmbeddedServletContainerFactory, JettyEmbeddedServletContainerFactory, or UndertowEmbeddedServletContainerFactory will have been auto-configured.

Note

You usually won't need to be aware of these implementation classes. Most applications will be auto-configured and the appropriate ApplicationContext and EmbeddedServletContainerFactory will be created on your behalf.

Customizing embedded servlet containers

Common servlet container settings can be configured using Spring Environment properties. Usually you would define the properties in your application.properties file.

Common server settings include:

- Network settings: listen port for incoming HTTP requests (server.port), interface address to bind to server.address, etc.
- Session settings: whether the session is persistent (server.session.persistence), session timeout (server.session.timeout), location of session data (server.session.store-dir) and session-cookie configuration (server.session.cookie.*).
- Error management: location of the error page (server.error.path), etc.
- <u>SSL</u>
- HTTP compression

Spring Boot tries as much as possible to expose common settings but this is not always possible. For those cases, dedicated namespaces offer server-specific customizations (see server.tomcat and server.undertow). For instance, <u>access logs</u> can be configured with specific features of the embedded servlet container.

Тір

See the <u>ServerProperties</u> class for a complete list.

Programmatic customization

If you need to configure your embedded servlet container programmatically you can register a Spring bean that implements the EmbeddedServletContainerCustomizer interface. EmbeddedServletContainerCustomizer provides access to the ConfigurableEmbeddedServletContainer which includes numerous customization setter methods.

```
import org.springframework.boot.context.embedded.*;
import org.springframework.stereotype.Component;
@Component
public class CustomizationBean implements EmbeddedServletContainerCustomizer {
    @Override
    public void customize(ConfigurableEmbeddedServletContainer container) {
        container.setPort(9000);
    }
}
```

Customizing ConfigurableEmbeddedServletContainer directly

If the above customization techniques are too limited, you can register the TomcatEmbeddedServletContainerFactory, JettyEmbeddedServletContainerFactory or UndertowEmbeddedServletContainerFactory bean yourself.

```
@Bean
public EmbeddedServletContainerFactory servletContainer() {
   TomcatEmbeddedServletContainerFactory factory = new TomcatEmbeddedServletContainerFactory();
   factory.setPort(9000);
   factory.setSessionTimeout(10, TimeUnit.MINUTES);
   factory.addErrorPages(new ErrorPage(HttpStatus.NOT_FOUND, "/notfound.html"));
   return factory;
}
```

Setters are provided for many configuration options. Several protected method 'hooks' are also provided should you need to do something more exotic. See the source code documentation for details.

JSP limitations

When running a Spring Boot application that uses an embedded servlet container (and is packaged as an executable archive), there are some limitations in the JSP support.

- With Tomcat it should work if you use war packaging, i.e. an executable war will work, and will also be deployable to a standard container (not limited to, but including Tomcat). An executable jar will not work because of a hard coded file pattern in Tomcat.
- Jetty does not currently work as an embedded container with JSPs.
- Undertow does not support JSPs.

There is a <u>JSP sample</u> so you can see how to set things up.

28. Security

If Spring Security is on the classpath then web applications will be secure by default with 'basic' authentication on all HTTP endpoints. To add method-level security to a web application you can also add @EnableGlobalMethodSecurity with your desired settings. Additional information can be found in the <u>Spring Security Reference</u>.

The default AuthenticationManager has a single user ('user' username and random password, printed at INFO level when the application starts up)

Using default security password: 78fa095d-3f4c-48b1-ad50-e24c31d5cf35

Note

If you fine tune your logging configuration, ensure that the org.springframework.boot.autoconfigure.security category is set to log INFO messages, otherwise the default password will not be printed.

You can change the password by providing a security.user.password. This and other useful properties are externalized via <u>SecurityProperties</u> (properties prefix "security").

The default security configuration is implemented in SecurityAutoConfiguration and in the classes imported from there (SpringBootWebSecurityConfiguration for web security and AuthenticationManagerConfiguration for authentication configuration which is also relevant in non-web applications). To switch off the default web security configuration completely you can add a bean with @EnableWebSecurity (this does not disable the authentication manager configuration). To customize it you normally use external properties and beans of type WebSecurityConfigurerAdapter (e.g. to add form-based login). To also switch off the authentication manager configuration you can add a bean of type AuthenticationManager, or else configure the global AuthenticationManager by autowiring an AuthenticationManagerBuilder into a method in one of your @Configuration classes. There are several secure applications in the <u>Spring Boot samples</u> to get you started with common use cases.

The basic features you get out of the box in a web application are:

- An AuthenticationManager bean with in-memory store and a single user (see SecurityProperties.User for the properties of the user).
- Ignored (insecure) paths for common static resource locations (/css/**, /js/**, /images/** and **/favicon.ico).
- HTTP Basic security for all other endpoints.
- Security events published to Spring's ApplicationEventPublisher (successful and unsuccessful authentication and access denied).
- Common low-level features (HSTS, XSS, CSRF, caching) provided by Spring Security are on by default.

All above switched modified of the can be on and off or using external properties (security.*). To override the access rules without changing any other auto-configured features add a @Bean of type WebSecurityConfigurerAdapter with @Order(SecurityProperties.ACCESS_OVERRIDE_ORDER).

28.1 OAuth2

If you have spring-security-oauth2 on your classpath you can take advantage of some autoconfiguration to make it easy to set up Authorization or Resource Server.

Authorization Server

To create an Authorization Server and grant access tokens you need to use @EnableAuthorizationServer and provide security.oauth2.client.client-id and security.oauth2.client.client-secret] properties. The client will be registered for you in an in-memory repository.

Having done that you will be able to use the client credentials to create an access token, for example:

\$ curl client:secret@localhost:8080/oauth/token -d grant_type=password -d username=user -d password=pwd

The basic auth credentials for the /token endpoint are the client-id and client-secret. The user credentials are the normal Spring Security user details (which default in Spring Boot to "user" and a random password).

To switch off the auto-configuration and configure the Authorization Server features yourself just add a @Bean of type AuthorizationServerConfigurer.

Resource Server

To use the access token you need a Resource Server (which can be the same as the Authorization Server). Creating a Resource Server is easy, just add @EnableResourceServer and provide some configuration to allow the server to decode access tokens. If your application is also an Authorization Server it already knows how to decode tokens, so there is nothing else to do. If your app is a standalone service then you need to give it some more configuration, one of the following options:

- security.oauth2.resource.user-info-uri to use the /me resource (e.g. <u>uaa.run.pivotal.io/userinfo</u> on PWS)
- security.oauth2.resource.token-info-uri to use the token decoding endpoint (e.g. <u>uaa.run.pivotal.io/check_token</u> on PWS).

If you specify both the user-info-uri and the token-info-uri then you can set a flag to say that one is preferred over the other (prefer-token-info=true is the default).

Alternatively (instead of user-info-uri or token-info-uri) if the tokens are JWTs you can configure a security.oauth2.resource.jwt.key-value to decode them locally (where the key is a verification key). The verification key value is either a symmetric secret or PEM-encoded RSA public key. If you don't have the key and it's public you can provide a URI where it can be downloaded (as a JSON object with a "value" field) with security.oauth2.resource.jwt.key-uri. E.g. on PWS:

```
$ curl https://uaa.run.pivotal.io/token_key
{"alg":"SHA256withRSA","value":"----BEGIN PUBLIC KEY----\nMIIBI...\n----END PUBLIC KEY----\n"}
```

Warning

If you use the security.oauth2.resource.jwt.key-uri the authorization server needs to be running when your application starts up. It will log a warning if it can't find the key, and tell you what to do to fix it.

28.2 Token Type in User Info

Google, and certain other 3rd party identity providers, are more strict about the token type name that is sent in the headers to the user info endpoint. The default is "Bearer" which suits most providers and matches the spec, but if you need to change it you can set security.oauth2.resource.token-type.

28.3 Customizing the User Info RestTemplate

If you have a user-info-uri, the resource server features use an OAuth2RestTemplate internally to fetch user details for authentication. This is provided as a qualified @Bean with id userInfoRestTemplate, but you shouldn't need to know that to just use it. The default should be fine for most providers, but occasionally you might need to add additional interceptors, or change the request authenticator (which is how the token gets attached to outgoing requests). To add a customization just create a bean of typeUserInfoRestTemplateCustomizer - it has a single method that will be called after the bean is created but before it is initialized. The rest template that is being customized here is *only* used internally to carry out authentication.

Tip

To set an RSA key value in YAML use the "pipe" continuation marker to split it over multiple lines ("|") and remember to indent the key value (it's a standard YAML language feature). Example:

```
security:
oauth2:
resource:
jwt:
keyValue: |
-----BEGIN PUBLIC KEY-----
MIIBIJANBgkqhkiG9w0BAQEFAAOCAQ8AMIIBCgKC...
-----END PUBLIC KEY-----
```

Client

To make your webapp into an OAuth2 client you can simply add @EnableOAuth2Client and Spring Boot will create an OAuth2RestTemplate for you to @Autowire. It uses the security.oauth2.client.* as credentials (the same as you might be using in the Authorization Server), but in addition it will need to know the authorization and token URIs in the Authorization Server. For example:

application.yml.

```
security:
    oauth2:
    client:
        clientId: bdlc0a783ccddlc9b9e4
        clientSecret: la9030fbca47a5b2c28e92f19050bb77824b5adl
        accessTokenUri: https://github.com/login/oauth/access_token
        userAuthorizationUri: https://github.com/login/oauth/authorize
        clientAuthenticationScheme: form
```

An application with this configuration will redirect to Github for authorization when you attempt to use the OAuth2RestTemplate. If you are already signed into Github you won't even notice that it has authenticated. These specific credentials will only work if your application is running on port 8080 (register your own client app in Github or other provider for more flexibility).

To limit the scope that the client asks for when it obtains an access token you can set security.oauth2.client.scope (comma separated or an array in YAML). By default the scope is empty and it is up to Authorization Server to decide what the defaults should be, usually depending on the settings in the client registration that it holds.

Note

There is also a setting for security.oauth2.client.client-authentication-scheme which defaults to "header" (but you might need to set it to "form" if, like Github for instance, your OAuth2 provider doesn't like header authentication). In fact, the security.oauth2.client.* properties are bound to an instance of AuthorizationCodeResourceDetails so all its properties can be specified.

Тір

In a non-web application you can still @Autowire an OAuth2RestOperations and it is still wired into the security.oauth2.client.* configuration. In this case it is a "client credentials token grant" you will be asking for if you use it (and there is no need to use @EnableOAuth2Client or @EnableOAuth2Sso). To switch it off, just remove the security.oauth2.client.client-id from your configuration (or make it the empty string).

Single Sign On

An OAuth2 Client can be used to fetch user details from the provider (if such features are available) and then convert them into an Authentication token for Spring Security. The Resource Server above support this via the user-info-uri property This is the basis for a Single Sign On (SSO) protocol based on OAuth2, and Spring Boot makes it easy to participate by providing an annotation @EnableOAuth2Sso. The Github client above can protect all its resources and authenticate using the Github /user/ endpoint, by adding that annotation and declaring where to find the endpoint (in addition to the security.oauth2.client.* configuration already listed above):

application.yml.

Since all paths are secure by default, there is no "home" page that you can show to unauthenticated users and invite them to login (by visiting the /login path, or the path specified by security.oauth2.sso.login-path).

To customize the access rules or paths to protect, so you can add a "home" page for instance, @EnableOAuth2Sso can be added to a WebSecurityConfigurerAdapter and the annotation will cause it to be decorated and enhanced with the necessary pieces to get the /login path working. For example, here we simply allow unauthenticated access to the home page at "/" and keep the default for everything else:

```
@Configuration
public class WebSecurityConfiguration extends WebSecurityConfigurerAdapter {
    @Override
    public void init(WebSecurity web) {
```

```
web.ignore("/");
}
@Override
protected void configure(HttpSecurity http) throws Exception {
    http.antMatcher("/**").authorizeRequests().anyRequest().authenticated();
}
```

28.4 Actuator Security

If the Actuator is also in use, you will find:

- The management endpoints are secure even if the application endpoints are insecure.
- Security events are transformed into AuditEvents and published to the AuditService.
- The default user will have the ADMIN role as well as the USER role.

The Actuator security features can be modified using external properties (management.security.*). To override the application access rules add a @Bean of type WebSecurityConfigurerAdapter and use @Order(SecurityProperties.ACCESS_OVERRIDE_ORDER) if you *don't* want to override the actuator access rules, or @Order(ManagementServerProperties.ACCESS_OVERRIDE_ORDER) if you *do* want to override the actuator access rules.

29. Working with SQL databases

The Spring Framework provides extensive support for working with SQL databases. From direct JDBC access using JdbcTemplate to complete 'object relational mapping' technologies such as Hibernate. Spring Data provides an additional level of functionality, creating Repository implementations directly from interfaces and using conventions to generate queries from your method names.

29.1 Configure a DataSource

Java's javax.sql.DataSource interface provides a standard method of working with database connections. Traditionally a DataSource uses a URL along with some credentials to establish a database connection.

Embedded Database Support

It's often convenient to develop applications using an in-memory embedded database. Obviously, inmemory databases do not provide persistent storage; you will need to populate your database when your application starts and be prepared to throw away data when your application ends.

Тір

The 'How-to' section includes a section on how to initialize a database

Spring Boot can auto-configure embedded <u>H2</u>, <u>HSQL</u> and <u>Derby</u> databases. You don't need to provide any connection URLs, simply include a build dependency to the embedded database that you want to use.

For example, typical POM dependencies would be:

```
<dependency>
<groupId>org.springframework.boot</groupId>
<artifactId>spring-boot-starter-data-jpa</artifactId>
</dependency>
<dependency>
<groupId>org.hsqldb</groupId>
<artifactId>hsqldb</artifactId>
<scope>runtime</scope>
</dependency>
```

Тір

If, for whatever reason, you do configure the connection URL for an embedded database, care should be taken to ensure that the database's automatic shutdown is disabled. If you're using H2 you should use DB_CLOSE_ON_EXIT=FALSE to do so. If you're using HSQLDB, you should ensure that shutdown=true is not used. Disabling the database's automatic shutdown allows Spring Boot to control when the database is closed, thereby ensuring that it happens once access to the database is no longer needed.

Note

You need a dependency on <code>spring-jdbc</code> for an embedded database to be auto-configured. In this example it's pulled in transitively via <code>spring-boot-starter-data-jpa</code>.

Connection to a production database

Production database connections can also be auto-configured using a pooling DataSource. Here's the algorithm for choosing a specific implementation:

- We prefer the Tomcat pooling DataSource for its performance and concurrency, so if that is available we always choose it.
- If HikariCP is available we will use it.
- If Commons DBCP is available we will use it, but we don't recommend it in production.
- Lastly, if Commons DBCP2 is available we will use it.

If you use the spring-boot-starter-jdbc or spring-boot-starter-data-jpa 'starter POMs' you will automatically get a dependency to tomcat-jdbc.

Note

You can bypass that algorithm completely and specify the connection pool to use via the spring.datasource.type property. Also, additional connection pools can always be configured manually. If you define your own DataSource bean, auto-configuration will not occur.

DataSource configuration is controlled by external configuration properties in spring.datasource.*. For example, you might declare the following section in application.properties:

```
spring.datasource.url=jdbc:mysql://localhost/test
spring.datasource.username=dbuser
spring.datasource.password=dbpass
spring.datasource.driver-class-name=com.mysql.jdbc.Driver
```

Тір

You often won't need to specify the driver-class-name since Spring boot can deduce it for most databases from the url.

Note

For a pooling DataSource to be created we need to be able to verify that a valid Driver class is available, so we check for that before doing anything. I.e. if you set spring.datasource.driver-class-name=com.mysql.jdbc.Driver then that class has to be loadable.

See <u>DataSourceProperties</u> for more of the supported options. These are the standard options that work regardless of the actual implementation. It is also possible to fine tune implementation-specific settings using the spring.datasource.* prefix, refer to the documentation of the connection pool implementation you are using for more details.

For instance, if you are using the <u>Tomcat connection pool</u> you could customize many additional settings:

Number of ms to wait before throwing an exception if no connection is available.
spring.datasource.max-wait=10000
Maximum number of active connections that can be allocated from this pool at the same time.
spring.datasource.max-active=50

```
# Validate the connection before borrowing it from the pool.
spring.datasource.test-on-borrow=true
```

Connection to a JNDI DataSource

If you are deploying your Spring Boot application to an Application Server you might want to configure and manage your DataSource using your Application Servers built-in features and access it using JNDI.

The spring.datasource.jndi-name property can be used as an alternative spring.datasource.username to the spring.datasource.url, and spring.datasource.password properties to access the DataSource from a specific JNDI location. For example, the following section in application.properties shows how you can access a JBoss AS defined DataSource:

spring.datasource.jndi-name=java:jboss/datasources/customers

29.2 Using JdbcTemplate

Spring's JdbcTemplate and NamedParameterJdbcTemplate classes are auto-configured and you can @Autowire them directly into your own beans:

```
import org.springframework.beans.factory.annotation.Autowired;
import org.springframework.jdbc.core.JdbcTemplate;
import org.springframework.stereotype.Component;
@Component
public class MyBean {
    private final JdbcTemplate jdbcTemplate;
    @Autowired
    public MyBean(JdbcTemplate jdbcTemplate) {
       this.jdbcTemplate = jdbcTemplate;
    }
    // ...
}
```

29.3 JPA and 'Spring Data'

The Java Persistence API is a standard technology that allows you to 'map' objects to relational databases. The spring-boot-starter-data-jpa POM provides a quick way to get started. It provides the following key dependencies:

- Hibernate One of the most popular JPA implementations.
- Spring Data JPA Makes it easy to implement JPA-based repositories.
- Spring ORMs Core ORM support from the Spring Framework.

Тір

We won't go into too many details of JPA or Spring Data here. You can follow the <u>'Accessing</u> <u>Data with JPA'</u> guide from <u>spring.io</u> and read the <u>Spring Data JPA</u> and <u>Hibernate</u> reference documentation.

Entity Classes

Traditionally, JPA 'Entity' classes are specified in a persistence.xml file. With Spring Boot this file is not necessary and instead 'Entity Scanning' is used. By default all packages below your main configuration class (the one annotated with @EnableAutoConfiguration or @SpringBootApplication) will be searched.

Any classes annotated with @Entity, @Embeddable or @MappedSuperclass will be considered. A typical entity class would look something like this:

```
package com.example.myapp.domain;
import java.io.Serializable;
import javax.persistence.*;
@Entity
public class City implements Serializable {
   @Td
   @GeneratedValue
   private Long id;
   @Column(nullable = false)
   private String name;
   @Column(nullable = false)
   private String state;
   // ... additional members, often include @OneToMany mappings
   protected City() {
       // no-args constructor required by JPA spec
       // this one is protected since it shouldn't be used directly
    }
    public City(String name, String state) {
       this.name = name;
        this.country = country;
   }
   public String getName() {
       return this.name;
    }
   public String getState() {
       return this.state;
    }
   // ... etc
}
```

Тір

You can customize entity scanning locations using the <code>@EntityScan</code> annotation. See the <u>Section 73.4, "Separate @Entity definitions from Spring configuration</u>" how-to.

Spring Data JPA Repositories

Spring Data JPA repositories are interfaces that you can define to access data. JPA queries are created automatically from your method names. For example, a CityRepository interface might declare a findAllByState(String state) method to find all cities in a given state.

For more complex queries you can annotate your method using Spring Data's <u>Query</u> annotation.

Spring Data repositories usually extend from the <u>Repository</u> or <u>CrudRepository</u> interfaces. If you are using auto-configuration, repositories will be searched from the package containing your main configuration class (the one annotated with @EnableAutoConfiguration or @SpringBootApplication) down.

Here is a typical Spring Data repository:

```
package com.example.myapp.domain;
import org.springframework.data.domain.*;
import org.springframework.data.repository.*;
public interface CityRepository extends Repository<City, Long> {
    Page<City> findAll(Pageable pageable);
    City findByNameAndCountryAllIgnoringCase(String name, String country);
}
```

Тір

We have barely scratched the surface of Spring Data JPA. For complete details check their reference documentation.

Creating and dropping JPA databases

By default, JPA databases will be automatically created **only** if you use an embedded database (H2, HSQL or Derby). You can explicitly configure JPA settings using spring.jpa.* properties. For example, to create and drop tables you can add the following to your application.properties.

spring.jpa.hibernate.ddl-auto=create-drop

Note

Hibernate's own internal property name for this (if you happen to remember it better) is hibernate.hbm2ddl.auto. You can set it, along with other Hibernate native properties, using spring.jpa.properties.* (the prefix is stripped before adding them to the entity manager). Example:

 ${\tt spring.jpa.properties.hibernate.globally_quoted_identifiers=true}$

passes hibernate.globally_quoted_identifiers to the Hibernate entity manager.

By default the DDL execution (or validation) is deferred until the ApplicationContext has started. There is also a spring.jpa.generate-ddl flag, but it is not used if Hibernate autoconfig is active because the ddl-auto settings are more fine-grained.

29.4 Using H2's web console

The <u>H2 database</u> provides a <u>browser-based console</u> that Spring Boot can auto-configure for you. The console will be auto-configured when the following conditions are met:

You are developing a web application

- com.h2database:h2 is on the classpath
- You are using <u>Spring Boot's developer tools</u>

Тір

If you are not using Spring Boot's developer tools, but would still like to make use of H2's console, then you can do so by configuring the <code>spring.h2.console.enabled</code> property with a value of true. The H2 console is only intended for use during development so care should be taken to ensure that <code>spring.h2.console.enabled</code> is not set to true in production.

Changing the H2 console's path

By default the console will be available at /h2-console. You can customize the console's path using the spring.h2.console.path property.

Securing the H2 console

When Spring Security is on the classpath and basic auth is enabled, the H2 console will be automatically secured using basic auth. The following properties can be used to customize the security configuration:

- security.user.role
- security.basic.authorize-mode
- security.basic.enabled

30. Using jOOQ

Java Object Oriented Querying (jOOQ) is a popular product from <u>Data Geekery</u> which generates Java code from your database, and lets you build type safe SQL queries through its fluent API. Both the commercial and open source editions can be used with Spring Boot.

30.1 Code Generation

In order to use jOOQ type-safe queries, you need to generate Java classes from your database schema. You can follow the instructions in the jOOQ user manual. If you are using the jooq-codegen-maven plugin (and you also use the spring-boot-starter-parent "parent POM") you can safely omit the plugin's <version> tag. You can also use Spring Boot defined version variables (e.g. h2.version) to declare the plugin's database dependency. Here's an example:

```
<plugin>
   <groupId>org.joog</groupId>
   <artifactId>jooq-codegen-maven</artifactId>
   <executions>
   </executions>
   <dependencies>
       <dependency>
            <groupId>com.h2database</groupId>
            <artifactId>h2</artifactId>
           <version>${h2.version}</version>
       </dependency>
   </dependencies>
    <configuration>
       <jdbc>
           <driver>org.h2.Driver</driver>
            <url>jdbc:h2:~/yourdatabase</url>
       </idbc>
       <generator>
           . . .
       </generator>
    </configuration>
</plugin>
```

30.2 Using DSLContext

The fluent API offered by jOOQ is initiated via the org.jooq.DSLContext interface. Spring Boot will auto-configure a DSLContext as a Spring Bean and connect it to your application DataSource. To use the DSLContext you can just @Autowire it:

```
@Component
public class JooqExample implements CommandLineRunner {
    private final DSLContext create;
    @Autowired
    public JooqExample(DSLContext dslContext) {
        this.create = dslContext;
    }
}
```

Тір

The jOOQ manual tends to use a variable named create to hold the DSLContext, we've done the same for this example.

You can then use the DSLContext to construct your queries:

```
public List<GregorianCalendar> authorsBornAfter1980() {
    return this.create.selectFrom(AUTHOR)
        .where(AUTHOR.DATE_OF_BIRTH.greaterThan(new GregorianCalendar(1980, 0, 1)))
        .fetch(AUTHOR.DATE_OF_BIRTH);
}
```

30.3 Customizing jOOQ

You can customize the SQL dialect used by jOOQ by setting spring.jooq.sql-dialect in your application.properties. For example, to specify Postgres you would add:

spring.jooq.sql-dialect=Postgres

More advanced customizations can be achieved by defining your own @Bean definitions which will be used when the jOOQ Configuration is created. You can define beans for the following jOOQ Types:

- ConnectionProvider
- TransactionProvider
- RecordMapperProvider
- RecordListenerProvider
- ExecuteListenerProvider
- VisitListenerProvider

You can also create your own org.jooq.Configuration@Bean if you want to take complete control of the jOOQ configuration.

31. Working with NoSQL technologies

Spring Data provides additional projects that help you access a variety of NoSQL technologies including <u>MongoDB</u>, <u>Neo4J</u>, <u>Elasticsearch</u>, <u>Solr</u>, <u>Redis</u>, <u>Gemfire</u>, <u>Couchbase</u> and <u>Cassandra</u>. Spring Boot provides auto-configuration for Redis, MongoDB, Elasticsearch, Solr and Cassandra; you can make use of the other projects, but you will need to configure them yourself. Refer to the appropriate reference documentation at <u>projects.spring.io/spring-data</u>.

31.1 Redis

<u>Redis</u> is a cache, message broker and richly-featured key-value store. Spring Boot offers basic autoconfiguration for the <u>Jedis</u> client library and abstractions on top of it provided by <u>Spring Data Redis</u>. There is a spring-boot-starter-redis 'Starter POM' for collecting the dependencies in a convenient way.

Connecting to Redis

You can inject an auto-configured RedisConnectionFactory, StringRedisTemplate or vanilla RedisTemplate instance as you would any other Spring Bean. By default the instance will attempt to connect to a Redis server using localhost:6379:

```
@Component
public class MyBean {
    private StringRedisTemplate template;
    @Autowired
    public MyBean(StringRedisTemplate template) {
        this.template = template;
    }
    // ...
}
```

If you add a @Bean of your own of any of the auto-configured types it will replace the default (except in the case of RedisTemplate the exclusion is based on the bean name 'redisTemplate' not its type). If commons-pool2 is on the classpath you will get a pooled connection factory by default.

31.2 MongoDB

<u>MongoDB</u> is an open-source NoSQL document database that uses a JSON-like schema instead of traditional table-based relational data. Spring Boot offers several conveniences for working with MongoDB, including the spring-boot-starter-data-mongodb 'Starter POM'.

Connecting to a MongoDB database

You can inject an auto-configured org.springframework.data.mongodb.MongoDbFactory to access Mongo databases. By default the instance will attempt to connect to a MongoDB server using the URL mongodb://localhost/test:

```
import org.springframework.data.mongodb.MongoDbFactory;
import com.mongodb.DB;
@Component
public class MyBean {
```

```
private final MongoDbFactory mongo;
@Autowired
public MyBean(MongoDbFactory mongo) {
    this.mongo = mongo;
}
// ...
public void example() {
    DB db = mongo.getDb();
    // ...
}
```

You can set spring.data.mongodb.uri property to change the URL and configure additional settings such as the replica set:

spring.data.mongodb.uri=mongodb://user:secret@mongol.example.com:12345,mongo2.example.com:23456/test

Alternatively, as long as you're using Mongo 2.x, specify a host/port. For example, you might declare the following in your application.properties:

```
spring.data.mongodb.host=mongoserver
spring.data.mongodb.port=27017
```

Note

}

spring.data.mongodb.host and spring.data.mongodb.port are not supported if you're
using the Mongo 3.0 Java driver. In such cases, spring.data.mongodb.uri should be used
to provide all of the configuration.

Tip

If spring.data.mongodb.port is not specified the default of 27017 is used. You could simply delete this line from the sample above.

Тір

If you aren't using Spring Data Mongo you can inject com.mongodb.Mongo beans instead of using MongoDbFactory.

You can also declare your own MongoDbFactory or Mongo bean if you want to take complete control of establishing the MongoDB connection.

MongoTemplate

Spring Data Mongo provides a <u>MongoTemplate</u> class that is very similar in its design to Spring's JdbcTemplate. As with JdbcTemplate Spring Boot auto-configures a bean for you to simply inject:

```
import org.springframework.beans.factory.annotation.Autowired;
import org.springframework.data.mongodb.core.MongoTemplate;
import org.springframework.stereotype.Component;
@Component
public class MyBean {
```

```
private final MongoTemplate mongoTemplate;
@Autowired
public MyBean(MongoTemplate mongoTemplate) {
    this.mongoTemplate = mongoTemplate;
}
// ...
```

See the MongoOperations Javadoc for complete details.

Spring Data MongoDB repositories

Spring Data includes repository support for MongoDB. As with the JPA repositories discussed earlier, the basic principle is that queries are constructed for you automatically based on method names.

In fact, both Spring Data JPA and Spring Data MongoDB share the same common infrastructure; so you could take the JPA example from earlier and, assuming that City is now a Mongo data class rather than a JPA @Entity, it will work in the same way.

```
package com.example.myapp.domain;
import org.springframework.data.domain.*;
import org.springframework.data.repository.*;
public interface CityRepository extends Repository<City, Long> {
    Page<City> findAll(Pageable pageable);
    City findByNameAndCountryAllIgnoringCase(String name, String country);
}
```

Тір

For complete details of Spring Data MongoDB, including its rich object mapping technologies, refer to their <u>reference documentation</u>.

Embedded Mongo

Spring Boot offers auto-configuration for <u>Embedded Mongo</u>. To use it in your Spring Boot application add a dependency on de.flapdoodle.embed:de.flapdoodle.embed.mongo.

The port that Mongo will listen on can be configured using the spring.data.mongodb.port property. To use a randomly allocated free port use a value of zero. The MongoClient created by MongoAutoConfiguration will be automatically configured to use the randomly allocated port.

If you have SLF4J on the classpath, output produced by Mongo will be automatically routed to a logger named org.springframework.boot.autoconfigure.mongo.embedded.EmbeddedMongo.

You can declare your own IMongodConfig and IRuntimeConfig beans to take control of the Mongo instance's configuration and logging routing.

31.3 Gemfire

<u>Spring Data Gemfire</u> provides convenient Spring-friendly tools for accessing the <u>Pivotal Gemfire</u> data management platform. There is a spring-boot-starter-data-gemfire 'Starter POM'

for collecting the dependencies in a convenient way. There is currently no auto-configuration support for Gemfire, but you can enable Spring Data Repositories with a <u>single annotation</u> (@EnableGemfireRepositories).

31.4 Solr

<u>Apache Solr</u> is a search engine. Spring Boot offers basic auto-configuration for the Solr 4 client library and abstractions on top of it provided by <u>Spring Data Solr</u>. There is a <u>spring-boot-starter-data-solr</u> 'Starter POM' for collecting the dependencies in a convenient way.

Тір

Solr 5 is currently not supported and the auto-configuration will not be enabled by a Solr 5 dependency.

Connecting to Solr

You can inject an auto-configured SolrServer instance as you would any other Spring bean. By default the instance will attempt to connect to a server using <u>localhost:8983/solr</u>:

```
@Component
public class MyBean {
    private SolrServer solr;
    @Autowired
    public MyBean(SolrServer solr) {
        this.solr = solr;
    }
    // ...
}
```

If you add a @Bean of your own of type SolrServer it will replace the default.

Spring Data Solr repositories

Spring Data includes repository support for Apache Solr. As with the JPA repositories discussed earlier, the basic principle is that queries are constructed for you automatically based on method names.

In fact, both Spring Data JPA and Spring Data Solr share the same common infrastructure; so you could take the JPA example from earlier and, assuming that City is now a @SolrDocument class rather than a JPA @Entity, it will work in the same way.

Тір

For complete details of Spring Data Solr, refer to their reference documentation.

31.5 Elasticsearch

<u>Elasticsearch</u> is an open source, distributed, real-time search and analytics engine. Spring Boot offers basic auto-configuration for the Elasticsearch and abstractions on top of it provided by <u>Spring</u> <u>Data Elasticsearch</u>. There is a spring-boot-starter-data-elasticsearch 'Starter POM' for collecting the dependencies in a convenient way.

Connecting to Elasticsearch

You can inject an auto-configured ElasticsearchTemplate or Elasticsearch Client instance as you would any other Spring Bean. By default the instance will attempt to connect to a local inmemory server (a NodeClient in Elasticsearch terms), but you can switch to a remote server (i.e. a TransportClient) by setting spring.data.elasticsearch.cluster-nodes to a commaseparated 'host:port' list.

```
@Component
public class MyBean {
    private ElasticsearchTemplate template;
    @Autowired
    public MyBean(ElasticsearchTemplate template) {
        this.template = template;
    }
    // ...
}
```

If you add a @Bean of your own of type ElasticsearchTemplate it will replace the default.

Spring Data Elasticsearch repositories

Spring Data includes repository support for Elasticsearch. As with the JPA repositories discussed earlier, the basic principle is that queries are constructed for you automatically based on method names.

In fact, both Spring Data JPA and Spring Data Elasticsearch share the same common infrastructure; so you could take the JPA example from earlier and, assuming that City is now an Elasticsearch @Document class rather than a JPA @Entity, it will work in the same way.

Тір

For complete details of Spring Data Elasticsearch, refer to their reference documentation.

31.6 Cassandra

<u>Cassandra</u> is an open source, distributed database management system designed to handle large amounts of data across many commodity servers. Spring Boot offers auto-configuration for Cassandra and abstractions on top of it provided by <u>Spring Data Cassandra</u>. There is a <u>spring-boot-starter-data-cassandra</u> 'Starter POM' for collecting the dependencies in a convenient way.

Connecting to Cassandra

You can inject an auto-configured CassandraTemplate or a Cassandra Session instance as you would any other Spring Bean. The spring.data.cassandra.* properties can be used to customize the connection. Generally you will to provide keyspace-name and contact-points properties:

```
spring.data.cassandra.keyspace-name=mykeyspace
spring.data.cassandra.contact-points=cassandrahost1,cassandrahost2
@Component
public class MyBean {
    private CassandraTemplate template;
```

```
@Autowired
public MyBean(CassandraTemplate template) {
    this.template = template;
}
// ...
}
```

If you add a @Bean of your own of type CassandraTemplate it will replace the default.

Spring Data Cassandra repositories

Spring Data includes basic repository support for Cassandra. Currently this is more limited than the JPA repositories discussed earlier, and will need to annotate finder methods with @guery.

Тір

For complete details of Spring Data Cassandra, refer to their reference documentation.

32. Caching

The Spring Framework provides support for transparently adding caching to an application. At its core, the abstraction applies caching to methods, reducing thus the number of executions based on the information available in the cache. The caching logic is applied transparently, without any interference to the invoker.

Note

Check the relevant section of the Spring Framework reference for more details.

In a nutshell, adding caching to an operation of your service is as easy as adding the relevant annotation to its method:

```
import javax.cache.annotation.CacheResult;
import org.springframework.stereotype.Component;
@Component
public class MathService {
    @CacheResult
    public int computePiDecimal(int i) {
        // ...
    }
}
```

Note

You can either use the standard JSR-107 (JCache) annotations or Spring's own caching annotations transparently. We strongly advise you however to not mix and match them.

Тір

It is also possible to <u>update</u> or <u>evict</u> data from the cache transparently.

32.1 Supported cache providers

The cache abstraction does not provide an actual store and relies on abstraction materialized by the org.springframework.cache.Cache and org.springframework.cache.CacheManager interfaces. Spring Boot auto-configures a suitable CacheManager according to the implementation as long as the caching support is enabled via the @EnableCaching annotation.

Тір

Use the spring-boot-starter-cache "Starter POM" to quickly add required caching dependencies. If you are adding dependencies manually you should note that certain implementations are only provided by the spring-context-support jar.

Spring Boot tries to detect the following providers (in this order):

- <u>Generic</u>
- JCache (JSR-107)

- EhCache 2.x
- Hazelcast
- Infinispan
- Redis
- Guava
- <u>Simple</u>

It is also possible to force the cache provider to use via the spring.cache.type property.

If the CacheManager is auto-configured by Spring Boot, you can further tune its configuration before it is fully initialized by exposing a bean implementing the CacheManagerCustomizer interface. The following set the cache names to use.

```
@Bean
public CacheManagerCustomizer<ConcurrentMapCacheManager> cacheManagerCustomizer() {
    return new CacheManagerCustomizer<ConcurrentMapCacheManager>() {
        @Override
        public void customize(ConcurrentMapCacheManager cacheManager) {
            cacheManager.setCacheNames(Arrays.asList("one", "two"));
        }
    };
};
```

Note

=== In the example above, a ConcurrentMapCacheManager is expected to be configured. If that is not the case, the customizer won't be invoked at all. You can have as many customizers as you want and you can also order them as usual using @Order or Ordered. ===

Generic

Generic caching is used if the context defines *at least* one org.springframework.cache.Cache bean, a CacheManager wrapping them is configured.

JCache

JCache is bootstrapped via the presence of a javax.cache.spi.CachingProvider on the classpath (i.e. a JSR-107 compliant caching library). It might happen than more that one provider is present, in which case the provider must be explicitly specified. Even if the JSR-107 standard does not enforce a standardized way to define the location of the configuration file, Spring Boot does its best to accommodate with implementation details.

```
# Only necessary if more than one provider is present
spring.cache.jcache.provider=com.acme.MyCachingProvider
spring.cache.jcache.config=classpath:acme.xml
```

Note

Since a cache library may offer both a native implementation and JSR-107 support Spring Boot will prefer the JSR-107 support so that the same features are available if you switch to a different JSR-107 implementation.

There are several ways to customize the underlying javax.cache.cacheManager:

- Caches can be created on startup via the spring.cache.cache-names property. If a custom javax.cache.configuration.Configuration bean is defined, it is used to customize them.
- org.springframework.boot.autoconfigure.cache.JCacheManagerCustomizer beans are invoked with the reference of the CacheManager for full customization.

Тір

If a standard javax.cache.CacheManager bean is defined, it is wrapped automatically in a org.springframework.cache.CacheManager implementation that the abstraction expects. No further customization is applied on it.

EhCache 2.x

EhCache 2.x is used if a file named ehcache.xml can be found at the root of the classpath. If EhCache 2.x and such file is present it is used to bootstrap the cache manager. An alternate configuration file can be provide a well using:

spring.cache.ehcache.config=classpath:config/another-config.xml

Hazelcast

Spring Boot has a <u>general support for Hazelcast</u>. If a HazelcastInstance has been auto-configured, it is automatically wrapped in a CacheManager.

If for some reason you need a different HazelcastInstance for caching, you can request Spring Boot to create a separate one that will be only used by the CacheManager:

spring.cache.hazelcast.config=classpath:config/my-cache-hazelcast.xml

Тір

If a separate HazelcastInstance is created that way, it is not registered in the application context.

Infinispan

Infinispan has no default configuration file location so it must be specified explicitly (or the default bootstrap is used).

spring.cache.infinispan.config=infinispan.xml

Caches can be created on startup via the spring.cache.cache-names property. If a custom ConfigurationBuilder bean is defined, it is used to customize them.

Redis

If Redis is available and configured, the RedisCacheManager is auto-configured. It is also possible to create additional caches on startup using the spring.cache.cache-names property.

Guava

If Guava is present, a GuavaCacheManager is auto-configured. Caches can be created on startup using the spring.cache.cache-names property and customized by one of the following (in this order):

1. A cache spec defined by spring.cache.guava.spec

2. A com.google.common.cache.CacheBuilderSpec bean is defined

3. A com.google.common.cache.CacheBuilder bean is defined

For instance, the following configuration creates a foo and bar caches with a maximum size of 500 and a *time to live* of 10 minutes

spring.cache.cache-names=foo,bar
spring.cache.guava.spec=maximumSize=500,expireAfterAccess=600s

Besides, if a com.google.common.cache.CacheLoader bean is defined, it is automatically associated to the GuavaCacheManager.

Simple

If none of these options worked out, a simple implementation using ConcurrentHashMap as cache store is configured. This is the default if no caching library is present in your application.

33. Messaging

The Spring Framework provides extensive support for integrating with messaging systems: from simplified use of the JMS API using JmsTemplate to a complete infrastructure to receive messages asynchronously. Spring AMQP provides a similar feature set for the 'Advanced Message Queuing Protocol' and Spring Boot also provides auto-configuration options for RabbitTemplate and RabbitMQ. There is also support for STOMP messaging natively in Spring WebSocket and Spring Boot has support for that through starters and a small amount of auto-configuration.

33.1 JMS

The javax.jms.ConnectionFactory interface provides a standard method of creating a javax.jms.Connection for interacting with a JMS broker. Although Spring needs a ConnectionFactory to work with JMS, you generally won't need to use it directly yourself and you can instead rely on higher level messaging abstractions (see the <u>relevant section</u> of the Spring Framework reference documentation for details). Spring Boot also auto-configures the necessary infrastructure to send and receive messages.

ActiveMQ support

Spring Boot can also configure a ConnectionFactory when it detects that ActiveMQ is available on the classpath. If the broker is present, an embedded broker is started and configured automatically (as long as no broker URL is specified through configuration).

ActiveMQ configuration is controlled by external configuration properties in spring.activemq.*.For
example, you might declare the following section in application.properties:

```
spring.activemq.broker-url=tcp://192.168.1.210:9876
spring.activemq.user=admin
spring.activemq.password=secret
```

See <u>ActiveMQProperties</u> for more of the supported options.

By default, ActiveMQ creates a destination if it does not exist yet, so destinations are resolved against their provided names.

Artemis support

Apache Artemis was formed in 2015 when HornetQ was donated to the Apache Foundation. All the features listed in the <u>the section called "HornetQ support</u>" section below can be applied to Artemis. Simply replace spring.hornetq.* properties with spring.artemis.* and use spring-boot-starter-artemis instead of spring-boot-starter-hornetq.

Note

You should not try and use Artemis and HornetQ and the same time.

HornetQ support

Spring Boot can auto-configure a ConnectionFactory when it detects that HornetQ is available on the classpath. If the broker is present, an embedded broker is started and configured automatically (unless the mode property has been explicitly set). The supported modes are: embedded (to make explicit that an embedded broker is required and should lead to an error if the broker is not available in

the classpath), and native to connect to a broker using the netty transport protocol. When the latter is configured, Spring Boot configures a ConnectionFactory connecting to a broker running on the local machine with the default settings.

Note

If you are using spring-boot-starter-hornetq the necessary dependencies to connect to an existing HornetQ instance are provided, as well as the Spring infrastructure to integrate with JMS. Adding org.hornetq:hornetq-jms-server to your application allows you to use the embedded mode.

HornetQ configuration is controlled by external configuration properties in spring.hornetq.*. For example, you might declare the following section in application.properties:

```
spring.hornetq.mode=native
spring.hornetq.host=192.168.1.210
spring.hornetq.port=9876
```

When embedding the broker, you can choose if you want to enable persistence, and the list of destinations that should be made available. These can be specified as a comma-separated list to create them with the default options; or you can define bean(s) of type org.hornetq.jms.server.config.JMSQueueConfiguration or org.hornetq.jms.server.config.TopicConfiguration, for advanced queue and topic configurations respectively.

See <u>HornetQProperties</u> for more of the supported options.

No JNDI lookup is involved at all and destinations are resolved against their names, either using the 'name' attribute in the HornetQ configuration or the names provided through configuration.

Using a JNDI ConnectionFactory

If you are running your application in an Application Server Spring Boot will attempt to locate a JMS ConnectionFactory using JNDI. By default the locations java:/JmsXA and java:/ XAConnectionFactory will be checked. You can use the spring.jms.jndi-name property if you need to specify an alternative location:

spring.jms.jndi-name=java:/MyConnectionFactory

Sending a message

Spring's JmsTemplate is auto-configured and you can autowire it directly into your own beans:

```
import org.springframework.beans.factory.annotation.Autowired;
import org.springframework.jms.core.JmsTemplate;
import org.springframework.stereotype.Component;
@Component
public class MyBean {
    private final JmsTemplate jmsTemplate;
    @Autowired
    public MyBean(JmsTemplate jmsTemplate) {
        this.jmsTemplate = jmsTemplate;
    }
}
```

// ..

Note

<u>JmsMessagingTemplate</u> can be injected in a similar manner.

Receiving a message

When the JMS infrastructure is present, any bean can be annotated with @JmsListener to create a listener endpoint. If no JmsListenerContainerFactory has been defined, a default one is configured automatically.

The default factory is transactional by default. If you are running in an infrastructure where a JtaTransactionManager is present, it will be associated to the listener container by default. If not, the sessionTransacted flag will be enabled. In that latter scenario, you can associate your local data store transaction to the processing of an incoming message by adding @Transactional on your listener method (or a delegate thereof). This will make sure that the incoming message is acknowledged once the local transaction has completed. This also includes sending response messages that have been performed on the same JMS session.

The following component creates a listener endpoint on the someQueue destination:

```
@Component
public class MyBean {
    @JmsListener(destination = "someQueue")
    public void processMessage(String content) {
        // ...
    }
}
```

Тір

Check the Javadoc of @EnableJms for more details.

If you need to create more JmsListenerContainerFactory instances or if you want to override the default, Spring Boot provides a DefaultJmsListenerContainerFactoryConfigurer that you can use to initialize a DefaultJmsListenerContainerFactory with the same settings as the one that is auto-configured.

For instance, the following exposes another factory that uses a specific MessageConverter:

```
@Configuration
static class JmsConfiguration {
    @Bean
    public DefaultJmsListenerContainerFactory myFactory(
        DefaultJmsListenerContainerFactoryConfigurer configurer) {
        DefaultJmsListenerContainerFactory factory =
            new DefaultJmsListenerContainerFactory();
        configurer.configure(factory, connectionFactory());
        factory.setMessageConverter(myMessageConverter());
        return factory;
    }
}
```

That you can use in any @JmsListener-annotated method as follows:

```
@Component
public class MyBean {
    @JmsListener(destination = "someQueue", **containerFactory="myFactory"**)
    public void processMessage(String content) {
        // ...
    }
}
```

33.2 AMQP

The Advanced Message Queuing Protocol (AMQP) is a platform-neutral, wire-level protocol for message-oriented middleware. The Spring AMQP project applies core Spring concepts to the development of AMQP-based messaging solutions.

RabbitMQ support

RabbitMQ is a lightweight, reliable, scalable and portable message broker based on the AMQP protocol. Spring uses RabbitMQ to communicate using the AMQP protocol.

RabbitMQ configuration is controlled by external configuration properties in spring.rabbitmq.*.For
example, you might declare the following section in application.properties:

```
spring.rabbitmg.host=localhost
spring.rabbitmg.port=5672
spring.rabbitmg.username=admin
spring.rabbitmg.password=secret
```

See <u>RabbitProperties</u> for more of the supported options.

Тір

Check Understanding AMQP, the protocol used by RabbitMQ for more details.

Sending a message

Spring's AmqpTemplate and AmqpAdmin are auto-configured and you can autowire them directly into your own beans:

```
import org.springframework.amqp.core.AmqpAdmin;
import org.springframework.amqp.core.AmqpTemplate;
import org.springframework.beans.factory.annotation.Autowired;
import org.springframework.stereotype.Component;
@Component
public class MyBean {
    private final AmqpAdmin amqpAdmin;
    private final AmqpTemplate amqpTemplate;
    @Autowired
    public MyBean(AmqpAdmin amqpAdmin, AmqpTemplate amqpTemplate) {
        this.amqpAdmin = amqpAdmin;
        this.amqpTemplate = amqpTemplate;
    }
    // ...
}
```

Note

<u>RabbitMessagingTemplate</u> can be injected in a similar manner.

Any org.springframework.amqp.core.Queue that is defined as a bean will be automatically used to declare a corresponding queue on the RabbitMQ instance if necessary.

Receiving a message

When the Rabbit infrastructure is present, any bean can be annotated with @RabbitListener to create a listener endpoint. If no RabbitListenerContainerFactory has been defined, a default one is configured automatically.

The following component creates a listener endpoint on the someQueue queue:

```
@Component
public class MyBean {
    @RabbitListener(queues = "someQueue")
    public void processMessage(String content) {
        // ...
    }
}
```

Тір

Check the Javadoc of @EnableRabbit for more details.

If you need to create more RabbitListenerContainerFactory instances or if you want to override the default, Spring Boot provides a SimpleRabbitListenerContainerFactoryConfigurer that you can use to initialize a SimpleRabbitListenerContainerFactory with the same settings as the one that is auto-configured.

For instance, the following exposes another factory that uses a specific MessageConverter:

```
@Configuration
static class RabbitConfiguration {
    @Bean
    public SimpleRabbitListenerContainerFactory myFactory(
        SimpleRabbitListenerContainerFactoryConfigurer configurer) {
        SimpleRabbitListenerContainerFactory factory =
            new SimpleRabbitListenerContainerFactory();
        configurer.configure(factory, connectionFactory);
        factory.setMessageConverter(myMessageConverter());
        return factory;
    }
}
```

That you can use in any @RabbitListener-annotated method as follows:

```
@Component
public class MyBean {
    @RabbitListener(queues = "someQueue", **containerFactory="myFactory"**)
    public void processMessage(String content) {
        // ...
    }
}
```

34. Sending email

The Spring Framework provides an easy abstraction for sending email using the JavaMailSender interface and Spring Boot provides auto-configuration for it as well as a starter module.

Тір

Check the <u>reference documentation</u> for a detailed explanation of how you can use JavaMailSender.

If spring.mail.host and the relevant libraries (as defined by spring-boot-starter-mail) are available, a default JavaMailSender is created if none exists. The sender can be further customized by configuration items from the spring.mail namespace, see the MailProperties for more details.

35. Distributed Transactions with JTA

Spring Boot supports distributed JTA transactions across multiple XA resources using either an <u>Atomikos</u> or <u>Bitronix</u> embedded transaction manager. JTA transactions are also supported when deploying to a suitable Java EE Application Server.

When a JTA environment is detected, Spring's JtaTransactionManager will be used to manage transactions. Auto-configured JMS, DataSource and JPA beans will be upgraded to support XA transactions. You can use standard Spring idioms such as @Transactional to participate in a distributed transaction. If you are within a JTA environment and still want to use local transactions you can set the spring.jta.enabled property to false to disable the JTA auto-configuration.

35.1 Using an Atomikos transaction manager

Atomikos is a popular open source transaction manager which can be embedded into your Spring Boot application. You can use the spring-boot-starter-jta-atomikos Starter POM to pull in the appropriate Atomikos libraries. Spring Boot will auto-configure Atomikos and ensure that appropriate depends-on settings are applied to your Spring beans for correct startup and shutdown ordering.

By default Atomikos transaction logs will be written to a transaction-logs directory in your application home directory (the directory in which your application jar file resides). You can customize this directory by setting a spring.jta.log-dir property in your application.properties file. Properties starting spring.jta. can also be used to customize the Atomikos UserTransactionServiceImp. See the <u>AtomikosProperties Javadoc</u> for complete details.

Note

To ensure that multiple transaction managers can safely coordinate the same resource managers, each Atomikos instance must be configured with a unique ID. By default this ID is the IP address of the machine on which Atomikos is running. To ensure uniqueness in production, you should configure the spring.jta.transaction-manager-id property with a different value for each instance of your application.

35.2 Using a Bitronix transaction manager

Bitronix is another popular open source JTA transaction manager implementation. You can use the spring-boot-starter-jta-bitronix starter POM to add the appropriate Bitronix dependencies to your project. As with Atomikos, Spring Boot will automatically configure Bitronix and post-process your beans to ensure that startup and shutdown ordering is correct.

By default Bitronix transaction log files (part1.btm and part2.btm) will be written to a transaction-logs directory in your application home directory. You can customize this directory by using the spring.jta.log-dir property. Properties starting spring.jta. are also bound to the bitronix.tm.Configuration bean, allowing for complete customization. See the <u>Bitronix</u> documentation for details.

Note

To ensure that multiple transaction managers can safely coordinate the same resource managers, each Bitronix instance must be configured with a unique ID. By default this ID is the IP address

of the machine on which Bitronix is running. To ensure uniqueness in production, you should configure the spring.jta.transaction-manager-id property with a different value for each instance of your application.

35.3 Using a Java EE managed transaction manager

If you are packaging your Spring Boot application as a war or ear file and deploying it to a Java EE application server, you can use your application servers built-in transaction manager. Spring Boot will attempt to auto-configure a transaction manager by looking at common JNDI locations (java:comp/UserTransaction, java:comp/TransactionManager etc). If you are using a transaction service provided by your application server, you will generally also want to ensure that all resources are managed by the server and exposed over JNDI. Spring Boot will attempt to auto-configure JMS by looking for a ConnectionFactory at the JNDI path java:/JmsXA or java:/XAConnectionFactory and you can use the spring.datasource.jndi-name property to configure your DataSource.

35.4 Mixing XA and non-XA JMS connections

When using JTA, the primary JMS ConnectionFactory bean will be XA aware and participate in distributed transactions. In some situations you might want to process certain JMS messages using a non-XA ConnectionFactory. For example, your JMS processing logic might take longer than the XA timeout.

If you want to use a non-XA ConnectionFactory you can inject the nonXaJmsConnectionFactory bean rather than the @Primary jmsConnectionFactory bean. For consistency the jmsConnectionFactory bean is also provided using the bean alias xaJmsConnectionFactory.

For example:

```
// Inject the primary (XA aware) ConnectionFactory
@Autowired
private ConnectionFactory defaultConnectionFactory;
// Inject the XA aware ConnectionFactory (uses the alias and injects the same as above)
@Autowired
@Qualifier("xaJmsConnectionFactory")
private ConnectionFactory xaConnectionFactory
@Autowired
@Qualifier("nonXaJmsConnectionFactory")
private ConnectionFactory")
private ConnectionFactory nonXaConnectionFactory;
```

35.5 Supporting an alternative embedded transaction manager

The <u>XAConnectionFactoryWrapper</u> and <u>XADataSourceWrapper</u> interfaces can be used to support alternative embedded transaction managers. The interfaces are responsible for wrapping XAConnectionFactory and XADataSource beans and exposing them as regular ConnectionFactory and DataSource beans which will transparently enroll in the distributed transaction. DataSource and JMS auto-configuration will use JTA variants as long as you have a JtaTransactionManager bean and appropriate XA wrapper beans registered within your ApplicationContext.

The <u>BitronixXAConnectionFactoryWrapper</u> and <u>BitronixXADataSourceWrapper</u> provide good examples of how to write XA wrappers.

36. Hazelcast

If hazelcast is on the classpath, Spring Boot will auto-configure an HazelcastInstance that you can inject in your application. The HazelcastInstance is only created if a configuration is found.

You can define a com.hazelcast.config.Config bean and we'll use that. If your configuration defines an instance name, we'll try to locate an existing instance rather than creating a new one.

You could also specify the hazelcast.xml configuration file to use via configuration:

spring.hazelcast.config=classpath:config/my-hazelcast.xml

Otherwise, Spring Boot tries to find the Hazelcast configuration from the default locations, that is hazelcast.xml in the working directory or at the root of the classpath. We also check if the hazelcast.config system property is set. Check the <u>Hazelcast documentation</u> for more details.

Note

Spring Boot also has an <u>explicit caching support for Hazelcast</u>. The HazelcastInstance is automatically wrapped in a CacheManager implementation if caching is enabled.

37. Spring Integration

Spring Integration provides abstractions over messaging and also other transports such as HTTP, TCP etc. If Spring Integration is available on your classpath it will be initialized through the @EnableIntegration annotation. Message processing statistics will be published over JMX if 'spring-integration-jmx' is also on the classpath. See the IntegrationAutoConfiguration class for more details.

38. Spring Session

Spring Session provides support for managing a user's session information. If you are writing a web application and Spring Session and Spring Data Redis are both on the classpath, Spring Boot will autoconfigure Spring Session through its @EnableRedisHttpSession. Session data will be stored in Redis and the session timeout can be configured using the server.session.timeout property.

39. Monitoring and management over JMX

Java Management Extensions (JMX) provide a standard mechanism to monitor and manage applications. By default Spring Boot will create an MBeanServer with bean id 'mbeanServer' and expose any of your beans that are annotated with Spring JMX annotations (@ManagedResource, @ManagedAttribute, @ManagedOperation).

See the <u>JmxAutoConfiguration</u> class for more details.

40. Testing

Spring Boot provides a number of useful tools for testing your application. The <code>spring-boot-starter-test POM</code> provides Spring Test, JUnit, Hamcrest and Mockito dependencies. There are also useful test utilities in the core <code>spring-boot</code> module under the <code>org.springframework.boot.test</code> package.

40.1 Test scope dependencies

If you use the spring-boot-starter-test 'Starter POM' (in the test scope), you will find the following provided libraries:

- Spring Test integration test support for Spring applications.
- JUnit The de-facto standard for unit testing Java applications.
- Hamcrest—A library of matcher objects (also known as constraints or predicates) allowing assertThat style JUnit assertions.
- Mockito A Java mocking framework.

These are common libraries that we generally find useful when writing tests. You are free to add additional test dependencies of your own if these don't suit your needs.

40.2 Testing Spring applications

One of the major advantages of dependency injection is that it should make your code easier to unit test. You can simply instantiate objects using the new operator without even involving Spring. You can also use *mock objects* instead of real dependencies.

Often you need to move beyond 'unit testing' and start 'integration testing' (with a Spring ApplicationContext actually involved in the process). It's useful to be able to perform integration testing without requiring deployment of your application or needing to connect to other infrastructure.

The Spring Framework includes a dedicated test module for just such integration testing. You can declare a dependency directly to org.springframework:spring-test or use the spring-boot-starter-test 'Starter POM' to pull it in transitively.

If you have not used the spring-test module before you should start by reading the <u>relevant section</u> of the Spring Framework reference documentation.

40.3 Testing Spring Boot applications

A Spring Boot application is just a Spring ApplicationContext so nothing very special has to be done to test it beyond what you would normally do with a vanilla Spring context. One thing to watch out for though is that the external properties, logging and other features of Spring Boot are only installed in the context by default if you use SpringApplication to create it.

Spring Boot provides a @SpringApplicationConfiguration annotation as an alternative to the standard spring-test @ContextConfiguration annotation. If you use @SpringApplicationConfiguration to configure the ApplicationContext used in your tests, it will be created via SpringApplication and you will get the additional Spring Boot features.

For example:

```
@RunWith(SpringJUnit4ClassRunner.class)
@SpringApplicationConfiguration(SampleDataJpaApplication.class)
public class CityRepositoryIntegrationTests {
    @Autowired
    CityRepository repository;
    // ...
}
```

Тір

The context loader guesses whether you want to test a web application or not (e.g. with MockMvc) by looking for the @WebIntegrationTest or @WebAppConfiguration annotations. (MockMvc and @WebAppConfiguration are part of spring-test).

If you want a web application to start up and listen on its normal port, so you can test it with HTTP (e.g. using RestTemplate), annotate your test class (or one of its superclasses) with @WebIntegrationTest. This can be very useful because it means you can test the full stack of your application, but also inject its components into the test class and use them to assert the internal state of the application after an HTTP interaction. For example:

```
@RunWith(SpringJUnit4ClassRunner.class)
@SpringApplicationConfiguration(SampleDataJpaApplication.class)
@WebIntegrationTest
public class CityRepositoryIntegrationTests {
    @Autowired
    CityRepository repository;
    RestTemplate restTemplate = new TestRestTemplate();
    // ... interact with the running server
}
```

Note

Spring's test framework will cache application contexts between tests. Therefore, as long as your tests share the same configuration, the time consuming process of starting and stopping the server will only happen once, regardless of the number of tests that actually run.

To change the port you can add environment properties to @WebIntegrationTest as colonor equals-separated name-value pairs, e.g. @WebIntegrationTest("server.port:9000"). Additionally you can set the server.port and management.port properties to 0 in order to run your integration tests using random ports. For example:

```
@RunWith(SpringJUnit4ClassRunner.class)
@SpringApplicationConfiguration(MyApplication.class)
@WebIntegrationTest({"server.port=0", "management.port=0"})
public class SomeIntegrationTests {
    // ...
}
```

Alternatively, you can use the randomPort convenience attribute to set server.port=0. For example:

```
@RunWith(SpringJUnit4ClassRunner.class)
@SpringApplicationConfiguration(MyApplication.class)
@WebIntegrationTest(randomPort = true)
public class SomeIntegrationTests {
    // ...
}
```

See <u>Section 70.4, "Discover the HTTP port at runtime"</u> for a description of how you can discover the actual port that was allocated for the duration of the tests.

Using Spock to test Spring Boot applications

If you wish to use Spock to test a Spring Boot application you should add a dependency on Spock's spock-spring module to your application's build. spock-spring integrates Spring's test framework into Spock.

Note

The annotations <u>described above</u> can be used with Spock, i.e. you can annotate your Specification with @WebIntegrationTest to suit the needs of your tests.

40.4 Test utilities

A few test utility classes are packaged as part of spring-boot that are generally useful when testing your application.

ConfigFileApplicationContextInitializer

ConfigFileApplicationContextInitializer is an ApplicationContextInitializer that can apply to your tests to load Spring Boot application.properties files. You can use this when you don't need the full features provided by @SpringApplicationConfiguration.

```
@ContextConfiguration(classes = Config.class,
initializers = ConfigFileApplicationContextInitializer.class)
```

EnvironmentTestUtils

EnvironmentTestUtils allows you to quickly add properties to a ConfigurableEnvironment or ConfigurableApplicationContext. Simply call it with key=value strings:

EnvironmentTestUtils.addEnvironment(env, "org=Spring", "name=Boot");

OutputCapture

OutputCapture is a JUnit Rule that you can use to capture System.out and System.err output. Simply declare the capture as a @Rule then use toString() for assertions:

```
import org.junit.Rule;
import org.junit.Test;
import org.springframework.boot.test.OutputCapture;
import static org.hamcrest.Matchers.*;
import static org.junit.Assert.*;
public class MyTest {
```

```
@Rule
public OutputCapture capture = new OutputCapture();
@Test
public void testName() throws Exception {
   System.out.println("Hello World!");
   assertThat(capture.toString(), containsString("World"));
}
```

TestRestTemplate

TestRestTemplate is a convenience subclass of Spring's RestTemplate that is useful in integration tests. You can get a vanilla template or one that sends Basic HTTP authentication (with a username and password). In either case the template will behave in a test-friendly way: not following redirects (so you can assert the response location), ignoring cookies (so the template is stateless), and not throwing exceptions on server-side errors. It is recommended, but not mandatory, to use Apache HTTP Client (version 4.3.2 or better), and if you have that on your classpath the TestRestTemplate will respond by configuring the client appropriately.

```
public class MyTest {
    RestTemplate template = new TestRestTemplate();
    @Test
    public void testRequest() throws Exception {
    HttpHeaders headers = template.getForEntity("http://myhost.com", String.class).getHeaders();
    assertThat(headers.getLocation().toString(), containsString("myotherhost"));
    }
}
```

41. Creating your own auto-configuration

If you work in a company that develops shared libraries, or if you work on an open-source or commercial library, you might want to develop your own auto-configuration. Auto-configuration classes can be bundled in external jars and still be picked-up by Spring Boot.

Auto-configuration can be associated to a "starter" that provides the auto-configuration code as well as the typical libraries that you would use with it. We will first cover what you need to know to build your own auto-configuration and we will move on to the <u>typical steps required to create a custom starter</u>.

Тір

A <u>demo project</u> is available to showcase how you can create a starter step by step.

41.1 Understanding auto-configured beans

Under the hood, auto-configuration is implemented with standard @Configuration classes. Additional @Conditional annotations are used to constrain when the auto-configuration should apply. Usually auto-configuration classes use @ConditionalOnClass and @ConditionalOnMissingBean annotations. This ensures that auto-configuration only applies when relevant classes are found and when you have not declared your own @Configuration.

You can browse the source code of <u>spring-boot-autoconfigure</u> to see the @Configuration classes that we provide (see the <u>META-INF/spring.factories</u> file).

41.2 Locating auto-configuration candidates

Spring Boot checks for the presence of a META-INF/spring.factories file within your published jar. The file should list your configuration classes under the EnableAutoConfiguration key.

```
org.springframework.boot.autoconfigure.EnableAutoConfiguration=\
com.mycorp.libx.autoconfigure.LibXAutoConfiguration,\
com.mycorp.libx.autoconfigure.LibXWebAutoConfiguration
```

You can use the <u>@AutoConfigureAfter</u> or <u>@AutoConfigureBefore</u> annotations if your configuration needs to be applied in a specific order. For example, if you provide web-specific configuration, your class may need to be applied after WebMvcAutoConfiguration.

If you want to order certain auto-configurations that shouldn't have any direct knowledge of each other, you can also use <code>@AutoconfigureOrder</code>. That annotation has the same semantic as the regular <code>@Order</code> annotation but provides a dedicated order for auto-configuration classes.

41.3 Condition annotations

You almost always want to include one or more @Conditional annotations on your auto-configuration class. The @ConditionalOnMissingBean is one common example that is used to allow developers to 'override' auto-configuration if they are not happy with your defaults.

Spring Boot includes a number of @Conditional annotations that you can reuse in your own code by annotating @Configuration classes or individual @Bean methods.

Class conditions

The @ConditionalOnClass and @ConditionalOnMissingClass annotations allows configuration to be included based on the presence or absence of specific classes. Due to the fact that annotation metadata is parsed using <u>ASM</u> you can actually use the value attribute to refer to the real class, even though that class might not actually appear on the running application classpath. You can also use the name attribute if you prefer to specify the class name using a String value.

Bean conditions

The @ConditionalOnBean and @ConditionalOnMissingBean annotations allow a bean to be included based on the presence or absence of specific beans. You can use the value attribute to specify beans by type, or name to specify beans by name. The search attribute allows you to limit the ApplicationContext hierarchy that should be considered when searching for beans.

Тір

You need to be very careful about the order that bean definitions are added as these conditions are evaluated based on what has been processed so far. For this reason, we recommend only using @ConditionalOnBean and @ConditionalOnMissingBean annotations on auto-configuration classes (since these are guaranteed to load after any user-define beans definitions have been added).

Note

@ConditionalOnBean and @ConditionalOnMissingBean do not prevent @Configuration classes from being created. Using these conditions at the class level is equivalent to marking each contained @Bean method with the annotation.

Property conditions

The @ConditionalOnProperty annotation allows configuration to be included based on a Spring Environment property. Use the prefix and name attributes to specify the property that should be checked. By default any property that exists and is not equal to false will be matched. You can also create more advanced checks using the havingValue and matchlfMissing attributes.

Resource conditions

The @ConditionalOnResource annotation allows configuration to be included only when a specific resource is present. Resources can be specified using the usual Spring conventions, for example, file:/home/user/test.dat.

Web application conditions

The @ConditionalOnWebApplication and @ConditionalOnNotWebApplication annotations allow configuration to be included depending on whether the application is a 'web application'. A web application is any application that is using a Spring WebApplicationContext, defines a session scope or has a StandardServletEnvironment.

SpEL expression conditions

The @ConditionalOnExpression annotation allows configuration to be included based on the result of a <u>SpEL expression</u>.

41.4 Creating your own starter

A full Spring Boot starter for a library may contain the following components:

- The autoconfigure module that contains the auto-configuration code.
- The starter module that provides a dependency to the autoconfigure module as well as the library and any additional dependencies that are typically useful. In a nutshell, adding the starter should be enough to start using that library.

Тір

You may combine the auto-configuration code and the dependency management in a single module if you don't need to separate those two concerns.

Naming

Please make sure to provide a proper namespace for your starter. Do not start your module names with spring-boot, even if you are using a different Maven groupId. We may offer an official support for the thing you're auto-configuring in the future.

Here is a rule of thumb. Let's assume that you are creating a starter for "acme", name the auto-configure module acme-spring-boot-autoconfigure and the starter acme-spring-boot-starter. If you only have one module combining the two, use acme-spring-boot-starter.

Besides, if your starter provides configuration keys, use a proper namespace for them. In particular, do not include your keys in the namespaces that Spring Boot uses (e.g. server, management, spring, etc). These are "ours" and we may improve/modify them in the future in such a way it could break your things.

Make sure to <u>trigger meta-data generation</u> so that IDE assistance is available for your keys as well. You may want to review the generated meta-data (META-INF/spring-configuration-metadata.json) to make sure your keys are properly documented.

Autoconfigure module

The autoconfigure module contains everything that is necessary to get started with the library. It may also contain configuration keys definition (@ConfigurationProperties) and any callback interface that can be used to further customize how the components are initialized.

Тір

You should mark the dependencies to the library as optional so that you can include the autoconfigure module in your projects more easily. If you do it that way, the library won't be provided and Spring Boot will back off by default.

Starter module

The starter is an empty jar, really. Its only purpose is to provide the necessary dependencies to work with the library; see it as an opinionated view of what is required to get started.

Do not make assumptions about the project in which your starter is added. If the library you are autoconfiguring typically requires other starters, mention them as well. Providing a proper set of *default* dependencies may be hard if the number of optional dependencies is high as you should avoid bringing unnecessary dependencies for a typical usage of the library.

42. WebSockets

Spring Boot provides WebSockets auto-configuration for embedded Tomcat (8 and 7), Jetty 9 and Undertow. If you're deploying a war file to a standalone container, Spring Boot assumes that the container will be responsible for the configuration of its WebSocket support.

Spring Framework provides <u>rich WebSocket support</u> that can be easily accessed via the springboot-starter-websocket module.

43. What to read next

If you want to learn more about any of the classes discussed in this section you can check out the <u>Spring</u> <u>Boot API documentation</u> or you can browse the <u>source code directly</u>. If you have specific questions, take a look at the <u>how-to</u> section.

If you are comfortable with Spring Boot's core features, you can carry on and read about <u>production-ready features</u>.

Part V. Spring Boot Actuator: Production-ready features

Spring Boot includes a number of additional features to help you monitor and manage your application when it's pushed to production. You can choose to manage and monitor your application using HTTP endpoints, with JMX or even by remote shell (SSH or Telnet). Auditing, health and metrics gathering can be automatically applied to your application.

Actuator HTTP endpoints are only available with a Spring MVC-based application. In particular, it will not work with Jersey <u>unless you enable Spring MVC as well.</u>

44. Enabling production-ready features

The <u>spring-boot-actuator</u> module provides all of Spring Boot's production-ready features. The simplest way to enable the features is to add a dependency to the <u>spring-boot-starter-actuator</u> 'Starter POM'.

Definition of Actuator

An actuator is a manufacturing term, referring to a mechanical device for moving or controlling something. Actuators can generate a large amount of motion from a small change.

To add the actuator to a Maven based project, add the following 'starter' dependency:

```
<dependencies>
    <dependency>
        <groupId>org.springframework.boot</groupId>
        <artifactId>spring-boot-starter-actuator</artifactId>
        </dependency>
</dependencies>
```

For Gradle, use the declaration:

```
dependencies {
    compile("org.springframework.boot:spring-boot-starter-actuator")
}
```

45. Endpoints

Actuator endpoints allow you to monitor and interact with your application. Spring Boot includes a number of built-in endpoints and you can also add your own. For example the health endpoint provides basic application health information.

The way that endpoints are exposed will depend on the type of technology that you choose. Most applications choose HTTP monitoring, where the ID of the endpoint is mapped to a URL. For example, by default, the health endpoint will be mapped to /health.

ID	Description	Sensitive Default
actuator	Provides a hypermedia-based "discovery page" for the other endpoints. Requires Spring HATEOAS to be on the classpath.	true
autoconfig	Displays an auto-configuration report showing all auto- configuration candidates and the reason why they 'were' or 'were not' applied.	true
beans	Displays a complete list of all the Spring beans in your application.	true
configprops	Displays a collated list of all @ConfigurationProperties.	true
docs	Displays documentation, including example requests and responses, for the Actuator's endpoints. Requires spring-boot-actuator-docs to be on the classpath.	false
dump	Performs a thread dump.	true
env	Exposes properties from Spring's ConfigurableEnvironment.	true
flyway	Shows any Flyway database migrations that have been applied.	true
health	Shows application health information (when the application is secure, a simple 'status' when accessed over an unauthenticated connection or full message details when authenticated).	false
info	Displays arbitrary application info.	false
liquibase	Shows any Liquibase database migrations that have been applied.	true
logfile	Returns the contents of the logfile (if logging.file or logging.path properties have been set). Only available via MVC. Supports the use of the HTTP Range header to retrieve part of the log file's content.	true
metrics	Shows 'metrics' information for the current application.	true

The following endpoints are available:

ID	Description	Sensitive Default
mappings	Displays a collated list of all @RequestMapping paths.	true
shutdown	Allows the application to be gracefully shutdown (not enabled by default).	true
trace	Displays trace information (by default the last few HTTP requests).	true

Note

Depending on how an endpoint is exposed, the sensitive property may be used as a security hint. For example, sensitive endpoints will require a username/password when they are accessed over HTTP (or simply disabled if web security is not enabled).

45.1 Customizing endpoints

Endpoints can be customized using Spring properties. You can change if an endpoint is enabled, if it is considered sensitive and even its id.

For example, here is an application.properties that changes the sensitivity and id of the beans endpoint and also enables shutdown.

```
endpoints.beans.id=springbeans
endpoints.beans.sensitive=false
endpoints.shutdown.enabled=true
```

Note

The prefix #endpoints + . + name" is used to uniquely identify the endpoint that is being configured.

By default, all endpoints except for shutdown are enabled. If you prefer to specifically "opt-in" endpoint enablement you can use the endpoints.enabled property. For example, the following will disable *all* endpoints except for info:

```
endpoints.enabled=false
endpoints.info.enabled=true
```

Likewise, you can also choose to globally set the "sensitive" flag of all endpoints. By default, the sensitive flag depends on the type of endpoint (see the table above). For example, to mark *all* endpoints as sensitive except info:

```
endpoints.sensitive=true
endpoints.info.sensitive=false
```

45.2 Hypermedia for actuator MVC endpoints

If <u>Spring HATEOAS</u> is on the classpath (e.g. through the spring-boot-starter-hateoas or if you are using <u>Spring Data REST</u>) then the HTTP endpoints from the Actuator are enhanced with hypermedia links, and a "discovery page" is added with links to all the endpoints. The "discovery page" is available on /actuator by default. It is implemented as an endpoint, allowing properties

to be used to configure its path (endpoints.actuator.path) and whether or not it is enabled (endpoints.actuator.enabled).

When a custom management context path is configured, the "discovery page" will automatically move from /actuator to the root of the management context. For example, if the management context path is /management then the discovery page will be available from /management.

If the <u>HAL Browser</u> is on the classpath via its webjar (org.webjars:hal-browser), or via the spring-data-rest-hal-browser then an HTML "discovery page", in the form of the HAL Browser, is also provided.

45.3 CORS support

<u>Cross-origin resource sharing</u> (CORS) is a <u>W3C specification</u> that allows you to specify in a flexible way what kind of cross domain requests are authorized. Actuator's MVC endpoints can be configured to support such scenarios.

CORS support is disabled by default and is only enabled once the endpoints.cors.allowedorigins property has been set. The configuration below permits GET and POST calls from the example.com domain:

```
endpoints.cors.allowed-origins=http://example.com
endpoints.cors.allowed-methods=GET,POST
```

Tip

Check EndpointCorsProperties for a complete list of options.

45.4 Adding custom endpoints

If you add a @Bean of type Endpoint then it will automatically be exposed over JMX and HTTP (if there is an server available). An HTTP endpoints can be customized further by creating a bean of type MvcEndpoint. Your MvcEndpoint is not a @Controller but it can use @RequestMapping (and @Managed*) to expose resources.

Тір

lf feature you are doing this as а library consider adding configuration class under а to /META-INF/spring.factories the kev org.springframework.boot.actuate.autoconfigure.EndpointWebMvcConfiguration. If you do that then the endpoint will move to a child context with all the other MVC endpoints if your users ask for a separate management port or address. A configuration declared this way can be a WebConfigurerAdapter if it wants to add static resources (for instance) to the management endpoints.

45.5 Health information

Health information can be used to check the status of your running application. It is often used by monitoring software to alert someone if a production system goes down. The default information exposed by the health endpoint depends on how it is accessed. For an unauthenticated connection in a secure application a simple 'status' message is returned, and for an authenticated connection additional details are also displayed (see Section 46.6, "HTTP health endpoint access restrictions" for HTTP details).

Health information is collected from all <u>HealthIndicator</u> beans defined in your ApplicationContext. Spring Boot includes a number of auto-configured HealthIndicators and you can also write your own.

45.6 Security with HealthIndicators

Information returned by HealthIndicators is often somewhat sensitive in nature. For example, you probably don't want to publish details of your database server to the world. For this reason, by default, only the health status is exposed over an unauthenticated HTTP connection. If you are happy for complete health information to always be exposed you can set endpoints.health.sensitive to false.

Health responses are also cached to prevent "denial of service" attacks. Use the endpoints.health.time-to-live property if you want to change the default cache period of 1000 milliseconds.

Auto-configured HealthIndicators

Name	Description
<u>CassandraHealt</u>	hChecks that a Cassandra database is up.
DiskSpaceHealt	<u>Checks for t</u> ow disk space.
DataSourceHeal	tChecksthata connection to DataSource can be obtained.
ElasticsearchHe	e <u>Checks.that.an.</u> ElasticSearch cluster is up.
<u>JmsHealthIndica</u>	a <u>Che</u> cks that a JMS broker is up.
MailHealthIndia	<u>cehec</u> ks that a mail server is up.
MongoHealthInd	<u>i Chreck</u> s that a Mongo database is up.
<u>RabbitHealthInc</u>	d <u>Checks</u> that a Rabbit server is up.
<u>RedisHealthInd</u>	<u>i Check</u> s that a Redis server is up.
SolrHealthIndic	<u>cehec</u> ks that a Solr server is up.

The following HealthIndicators are auto-configured by Spring Boot when appropriate:

Тір

It is possible to disable them all using the management.health.defaults.enabled property.

Writing custom HealthIndicators

To provide custom health information you can register Spring beans that implement the <u>HealthIndicator</u> interface. You need to provide an implementation of the health() method and return a Health response. The Health response should include a status and can optionally include additional details to be displayed.

```
import org.springframework.boot.actuate.health.HealthIndicator;
import org.springframework.stereotype.Component;
```

```
@Component
public class MyHealthIndicator implements HealthIndicator {
    @Override
    public Health health() {
        int errorCode = check(); // perform some specific health check
        if (errorCode != 0) {
            return Health.down().withDetail("Error Code", errorCode).build();
        }
        return Health.up().build();
    }
}
```

Note

The identifier for a given HealthIndicator is the name of the bean without the HealthIndicator suffix if it exists. In the example above, the health information will be available in an entry named my.

In addition to Spring Boot's predefined <u>Status</u> types, it is also possible for Health to return a custom Status that represents a new system state. In such cases a custom implementation of the <u>HealthAggregator</u> interface also needs to be provided, or the default implementation has to be configured using the management.health.status.order configuration property.

For example, assuming a new Status with code FATAL is being used in one of your HealthIndicator implementations. To configure the severity order add the following to your application properties:

management.health.status.order=DOWN, OUT_OF_SERVICE, UNKNOWN, UP

You might also want to register custom status mappings with the HealthMvcEndpoint if you access the health endpoint over HTTP. For example you could map FATAL to HttpStatus.SERVICE_UNAVAILABLE.

45.7 Custom application info information

You can customize the data exposed by the info endpoint by setting info.* Spring properties. All Environment properties under the info key will be automatically exposed. For example, you could add the following to your application.properties:

```
info.app.name=MyService
info.app.description=My awesome service
info.app.version=1.0.0
```

Automatically expand info properties at build time

Rather than hardcoding some properties that are also specified in your project's build configuration, you can automatically expand info properties using the existing build configuration instead. This is possible in both Maven and Gradle.

Automatic property expansion using Maven

You can automatically expand info properties from the Maven project using resource filtering. If you use the spring-boot-starter-parent you can then refer to your Maven 'project properties' via @..@ placeholders, e.g.

```
project.artifactId=myproject
project.name=Demo
project.version=X.X.X.X
project.description=Demo project for info endpoint
info.build.artifact=@project.artifactId@
info.build.name=@project.artifactId@
info.build.description=@project.description@
info.build.version=@project.version@
```

Тір

The spring-boot:run can add src/main/resources directly to the classpath (for hot reloading purposes) if you enable the addResources flag. This circumvents the resource filtering and this feature. You can use the exec: java goal instead or customize the plugin's configuration, see the plugin usage page for more details.

If you don't use the starter parent, in your pom.xml you need (inside the <build/> element):

```
<resources>
    <resource>
        <directory>src/main/resources</directory>
        <filtering>true</filtering>
        </resource>
</resources>
```

and (inside <plugins/>):

```
<plugin>
<groupId>org.apache.maven.plugins</groupId>
<artifactId>maven-resources-plugin</artifactId>
<version>2.6</version>
<configuration>
<delimiters>
<delimiters>
</delimiters>
</delimiters>
</configuration>
</plugin>
```

Note

The useDefaultDelimiters property is important if you are using standard Spring placeholders in your configuration (e.g. f_{00}). These may be expanded by the build if that property is not set to false.

Automatic property expansion using Gradle

You can automatically expand info properties from the Gradle project by configuring the Java plugin's processResources task to do so:

```
processResources {
    expand(project.properties)
}
```

You can then refer to your Gradle project's properties via placeholders, e.g.

```
info.build.name=${name}
info.build.description=${description}
info.build.version=${version}
```

Note

Gradle's expand method uses Groovy's SimpleTemplateEngine which transforms $\{..\}$ tokens. The $\{..\}$ style conflicts with Spring's own property placeholder mechanism. To use Spring property placeholders together with automatic expansion the Spring property placeholders need to be escaped like $\{..\}$.

Git commit information

Another useful feature of the info endpoint is its ability to publish information about the state of your git source code repository when the project was built. If a git.properties file is contained in your jar the git.branch and git.commit properties will be loaded.

For Maven users the spring-boot-starter-parent POM includes a pre-configured plugin to generate a git.properties file. Simply add the following declaration to your POM:

Gradle users can achieve the same result using the $\underline{gradle-git-properties}$ plugin

```
plugins {
    id "com.gorylenko.gradle-git-properties" version "1.4.6"
}
```

46. Monitoring and management over HTTP

If you are developing a Spring MVC application, Spring Boot Actuator will auto-configure all enabled endpoints to be exposed over HTTP. The default convention is to use the id of the endpoint as the URL path. For example, health is exposed as /health.

46.1 Securing sensitive endpoints

If you add 'Spring Security' to your project, all sensitive endpoints exposed over HTTP will be protected. By default 'basic' authentication will be used with the username user and a generated password (which is printed on the console when the application starts).

Тір

Generated passwords are logged as the application starts. Search for 'Using default security password'.

You can use Spring properties to change the username and password and to change the security role required to access the endpoints. For example, you might set the following in your application.properties:

```
security.user.name=admin
security.user.password=secret
management.security.role=SUPERUSER
```

Тір

If you don't use Spring Security and your HTTP endpoints are exposed publicly, you should carefully consider which endpoints you enable. See <u>Section 45.1</u>, "Customizing endpoints" for details of how you can set endpoints.enabled to false then "opt-in" only specific endpoints.

46.2 Customizing the management endpoint paths

Sometimes it is useful to group all management endpoints under a single path. For example, your application might already use /info for another purpose. You can use the management.context-path property to set a prefix for your management endpoint:

management.context-path=/manage

The application.properties example above will change the endpoint from /{id} to /manage/ {id} (e.g. /manage/info).

You can also change the "id" of an endpoint (using endpoints. {name}.id) which then changes the default resource path for the MVC endpoint. Legal endpoint ids are composed only of alphanumeric characters (because they can be exposed in a number of places, including JMX object names, where special characters are forbidden). The MVC path can be changed separately by configuring endpoints. {name}.path, and there is no validation on those values (so you can use anything that is legal in a URL path). For example, to change the location of the /health endpoint to /ping/me you can set endpoints.health.path=/ping/me.

Тір

If you provide a custom MvcEndpoint remember to include a settable path property, and default it to /{id} if you want your code to behave like the standard MVC endpoints. (Take a look at the HealthMvcEndpoint to see how you might do that.) If your custom endpoint is an Endpoint (not an MvcEndpoint) then Spring Boot will take care of the path for you.

46.3 Customizing the management server port

Exposing management endpoints using the default HTTP port is a sensible choice for cloud based deployments. If, however, your application runs inside your own data center you may prefer to expose endpoints using a different HTTP port.

The management.port property can be used to change the HTTP port.

management.port=8081

Since your management port is often protected by a firewall, and not exposed to the public you might not need security on the management endpoints, even if your main application is secure. In that case you will have Spring Security on the classpath, and you can disable management security like this:

management.security.enabled=false

(If you don't have Spring Security on the classpath then there is no need to explicitly disable the management security in this way, and it might even break the application.)

46.4 Customizing the management server address

You can customize the address that the management endpoints are available on by setting the management.address property. This can be useful if you want to listen only on an internal or ops-facing network, or to only listen for connections from localhost.

Note

You can only listen on a different address if the port is different to the main server port.

Here is an example application.properties that will not allow remote management connections:

```
management.port=8081
management.address=127.0.0.1
```

46.5 Disabling HTTP endpoints

If you don't want to expose endpoints over HTTP you can set the management port to -1:

management.port=-1

46.6 HTTP health endpoint access restrictions

The information exposed by the health endpoint varies depending on whether or not it's accessed anonymously, and whether or not the enclosing application is secure. By default, when accessed anonymously in a secure application, any details about the server's health are hidden and the endpoint will simply indicate whether or not the server is up or down. Furthermore, when accessed anonymously, the response is cached for a configurable period to prevent the endpoint being used in a denial of service attack. The endpoints.health.time-to-live property is used to configure the caching period in milliseconds. It defaults to 1000, i.e. one second.

The above-described restrictions can be enhanced, thereby allowing only authenticated users full access to the health endpoint in a secure application. To do so, set endpoints.health.sensitive to true. Here's a summary of behavior (with default sensitive flag value "false" indicated in bold):

management.securit	yenednabinets.health.s	eduauthenticated	Authenticated
false	false	Full content	Full content
false	true	Status only	Full content
true	false	Status only	Full content
true	true	No content	Full content

47. Monitoring and management over JMX

Java Management Extensions (JMX) provide a standard mechanism to monitor and manage applications. By default Spring Boot will expose management endpoints as JMX MBeans under the org.springframework.boot domain.

47.1 Customizing MBean names

The name of the MBean is usually generated from the id of the endpoint. For example the health endpoint is exposed as org.springframework.boot/Endpoint/healthEndpoint.

If your application contains more than one Spring ApplicationContext you may find that names clash. To solve this problem you can set the endpoints.jmx.unique-names property to true so that MBean names are always unique.

You can also customize the JMX domain under which endpoints are exposed. Here is an example application.properties:

```
endpoints.jmx.domain=myapp
endpoints.jmx.unique-names=true
```

47.2 Disabling JMX endpoints

If you don't want to expose endpoints over JMX you can set the endpoints.jmx.enabled property to false:

endpoints.jmx.enabled=false

47.3 Using Jolokia for JMX over HTTP

Jolokia is a JMX-HTTP bridge giving an alternative method of accessing JMX beans. To use Jolokia, simply include a dependency to org.jolokia:jolokia-core. For example, using Maven you would add the following:

```
<dependency>
    <groupId>org.jolokia</groupId>
    <artifactId>jolokia-core</artifactId>
    </dependency>
```

Jolokia can then be accessed using /jolokia on your management HTTP server.

Customizing Jolokia

Jolokia has a number of settings that you would traditionally configure using servlet parameters. With Spring Boot you can use your application.properties, simply prefix the parameter with jolokia.config.:

jolokia.config.debug=true

Disabling Jolokia

If you are using Jolokia but you don't want Spring Boot to configure it, simply set the endpoints.jolokia.enabled property to false:

endpoints.jolokia.enabled=false

48. Monitoring and management using a remote shell

Spring Boot supports an integrated Java shell called 'CRaSH'. You can use CRaSH to ssh or telnet into your running application. To enable remote shell support, add the following dependency to your project:

```
<dependency>
    <groupId>org.springframework.boot</groupId>
    <artifactId>spring-boot-starter-remote-shell</artifactId>
    </dependency>
```

Тір

If you want to also enable telnet access you will additionally need a dependency on org.crsh:crsh.shell.telnet.

Note

CRaSH requires to run with a JDK as it compiles commands on the fly. If a basic help command fails, you are probably running with a JRE.

48.1 Connecting to the remote shell

By default the remote shell will listen for connections on port 2000. The default user is user and the default password will be randomly generated and displayed in the log output. If your application is using Spring Security, the shell will use <u>the same configuration</u> by default. If not, a simple authentication will be applied and you should see a message like this:

Using default password for shell access: ec03e16c-4cf4-49ee-b745-7c8255c1dd7e

Linux and OSX users can use ssh to connect to the remote shell, Windows users can download and install <u>PuTTY</u>.

Type help for a list of commands. Spring Boot provides metrics, beans, autoconfig and endpoint commands.

Remote shell credentials

You can use the shell.auth.simple.user.name and shell.auth.simple.user.password properties to configure custom connection credentials. It is also possible to use a 'Spring Security' AuthenticationManager to handle login duties. See the <u>CrshAutoConfiguration</u> and <u>ShellProperties</u> Javadoc for full details.

48.2 Extending the remote shell

The remote shell can be extended in a number of interesting ways.

Remote shell commands

You can write additional shell commands using Groovy or Java (see the CRaSH documentation for details). By default Spring Boot will search for commands in the following locations:

```
• classpath*:/commands/**
```

```
• classpath*:/crash/commands/**
```

Tip

You can change the search path by settings a shell.command-path-patterns property.

Here is a simple 'hello' command that could be loaded from src/main/resources/commands/ hello.groovy

```
package commands
import org.crsh.cli.Command
import org.crsh.cli.Usage
import org.crsh.command.InvocationContext
class hello {
    @Usage("Say Hello")
    @Command
    def main(InvocationContext context) {
        return "Hello"
    }
}
```

Spring Boot adds some additional attributes to InvocationContext that you can access from your command:

Attribute Name	Description
spring.boot.version	The version of Spring Boot
spring.version	The version of the core Spring Framework
spring.beanfactory	Access to the Spring BeanFactory
spring.environment	Access to the Spring Environment

Remote shell plugins

In addition to new commands, it is also possible to extend other CRaSH shell features. All Spring Beans that extend org.crsh.plugin.CRaSHPlugin will be automatically registered with the shell.

For more information please refer to the <u>CRaSH reference documentation</u>.

49. Metrics

Spring Boot Actuator includes a metrics service with 'gauge' and 'counter' support. A 'gauge' records a single value; and a 'counter' records a delta (an increment or decrement). Spring Boot Actuator also provides a <u>PublicMetrics</u> interface that you can implement to expose metrics that you cannot record via one of those two mechanisms. Look at <u>SystemPublicMetrics</u> for an example.

Metrics for all HTTP requests are automatically recorded, so if you hit the metrics endpoint you should see a response similar to this:

Here we can see basic memory, heap, class loading, processor and thread pool information along with some HTTP metrics. In this instance the root ('/') and /metrics URLs have returned HTTP 200 responses 20 and 3 times respectively. It also appears that the root URL returned HTTP 401 (unauthorized) 4 times. The double asterisks (star-star) comes from a request matched by Spring MVC as /** (normally a static resource).

The gauge shows the last response time for a request. So the last request to root took 2ms to respond and the last to /metrics took 3ms.

Note

In this example we are actually accessing the endpoint over HTTP using the /metrics URL, this explains why metrics appears in the response.

49.1 System metrics

The following system metrics are exposed by Spring Boot:

- The total system memory in KB (mem)
- The amount of free memory in KB (mem.free)
- The number of processors (processors)
- The system uptime in milliseconds (uptime)
- The application context uptime in milliseconds (instance.uptime)
- The average system load (systemload.average)
- Heap information in KB (heap, heap.committed, heap.init, heap.used)
- Thread information (threads, thread.peak, thread.daemon)
- Class load information (classes, classes.loaded, classes.unloaded)
- Garbage collection information (gc.xxx.count, gc.xxx.time)

49.2 DataSource metrics

The following metrics are exposed for each supported DataSource defined in your application:

- The number of active connections (datasource.xxx.active)
- The current usage of the connection pool (datasource.xxx.usage).

All data source metrics share the datasource. prefix. The prefix is further qualified for each data source:

- If the data source is the primary data source (that is either the only available data source or the one flagged @Primary amongst the existing ones), the prefix is datasource.primary.
- If the data source bean name ends with DataSource, the prefix is the name of the bean without DataSource (i.e. datasource.batch for batchDataSource).
- In all other cases, the name of the bean is used.

It is possible to override part or all of those defaults by registering a bean with a customized version of DataSourcePublicMetrics. By default, Spring Boot provides metadata for all supported data sources; you can add additional DataSourcePoolMetadataProvider beans if your favorite data source isn't supported out of the box. See DataSourcePoolMetadataProvidersConfiguration for examples.

49.3 Cache metrics

The following metrics are exposed for each supported cache defined in your application:

- The current size of the cache (cache.xxx.size)
- Hit ratio (cache.xxx.hit.ratio)
- Miss ratio (cache.xxx.miss.ratio)

Note

Cache providers do not expose the hit/miss ratio in a consistent way. While some expose an **aggregated** value (i.e. the hit ratio since the last time the stats were cleared), others expose a

temporal value (i.e. the hit ratio of the last second). Check your caching provider documentation for more details.

If two different cache managers happen to define the same cache, the name of the cache is prefixed by the name of the CacheManager bean.

It is possible to override part or all of those defaults by registering a bean with a customized version of CachePublicMetrics. By default, Spring Boot provides cache statistics for EhCache, Hazelcast, Infinispan, JCache and Guava. You can add additional CacheStatisticsProvider beans if your favorite caching library isn't supported out of the box. See CacheStatisticsAutoConfiguration for examples.

49.4 Tomcat session metrics

If you are using Tomcat as your embedded servlet container, session metrics will automatically be exposed. The httpsessions.active and httpsessions.max keys provide the number of active and maximum sessions.

49.5 Recording your own metrics

To record your own metrics inject a <u>CounterService</u> and/or <u>GaugeService</u> into your bean. The CounterService exposes increment, decrement and reset methods; the GaugeService provides a submit method.

Here is a simple example that counts the number of times that a method is invoked:

```
import org.springframework.beans.factory.annotation.Autowired;
import org.springframework.boot.actuate.metrics.CounterService;
import org.springframework.stereotype.Service;
@Service
public class MyService {
    private final CounterService counterService;
    @Autowired
    public MyService(CounterService counterService) {
        this.counterService = counterService;
    }
    public void exampleMethod() {
        this.counterService.increment("services.system.myservice.invoked");
    }
}
```

Тір

You can use any string as a metric name but you should follow guidelines of your chosen store/ graphing technology. Some good guidelines for Graphite are available on <u>Matt Aimonetti's Blog</u>.

49.6 Adding your own public metrics

To add additional metrics that are computed every time the metrics endpoint is invoked, simply register additional PublicMetrics implementation bean(s). By default, all such beans are gathered by the endpoint. You can easily change that by defining your own MetricsEndpoint.

49.7 Special features with Java 8

The default implementation of GaugeService and CounterService provided by Spring Boot depends on the version of Java that you are using. With Java 8 (or better) the implementation switches to a high-performance version optimized for fast writes, backed by atomic in-memory buffers, rather than by the immutable but relatively expensive Metric<?> type (counters are approximately 5 times faster and gauges approximately twice as fast as the repository-based implementations). The Dropwizard metrics services (see below) are also very efficient even for Java 7 (they have backports of some of the Java 8 concurrency libraries), but they do not record timestamps for metric values. If performance of metric gathering is a concern then it is always advisable to use one of the high-performance options, and also to only read metrics infrequently, so that the writes are buffered locally and only read when needed.

Note

The old MetricRepository and its InMemoryMetricRepository implementation are not used by default if you are on Java 8 or if you are using Dropwizard metrics.

49.8 Metric writers, exporters and aggregation

Spring Boot provides a couple of implementations of a marker interface called Exporter which can be used to copy metric readings from the in-memory buffers to a place where they can be analyzed and displayed. Indeed, if you provide a <code>@Bean</code> that implements the <code>MetricWriter</code> interface (or <code>GaugeWriter</code> for simple use cases) and mark it <code>@ExportMetricWriter</code>, then it will automatically be hooked up to an Exporter and fed metric updates every 5 seconds (configured via spring.metrics.export.delay-millis). In addition, any <code>MetricReader</code> that you define and mark as <code>@ExportMetricReader</code> will have its values exported by the default exporter.

The default exporter is a MetricCopyExporter which tries to optimize itself by not copying values that haven't changed since it was last called (the optimization can be switched off using a flag spring.metrics.export.send-latest). Note also that the Dropwizard MetricRegistry has no support for timestamps, so the optimization is not available if you are using Dropwizard metrics (all metrics will be copied on every tick).

The default values for the export trigger (delay-millis, includes, excludes and send-latest) can be set as spring.metrics.export.*. Individual values for specific MetricWriters can be set as spring.metrics.export.triggers.<name>.* where <name> is a bean name (or pattern for matching bean names).

Warning

The automatic export of metrics is disabled if you switch off the default MetricRepository (e.g. by using Dropwizard metrics). You can get back the same functionality be declaring a bean of your own of type MetricReader and declaring it to be @ExportMetricReader.

Example: Export to Redis

If you provide a @Bean of type RedisMetricRepository and mark it @ExportMetricWriter the metrics are exported to a Redis cache for aggregation. The RedisMetricRepository has two important parameters to configure it for this purpose: prefix and key (passed into its constructor). It is best to use a prefix that is unique to the application instance (e.g. using a random value and maybe the logical name of the application to make it possible to correlate with other instances of the

same application). The "key" is used to keep a global index of all metric names, so it should be unique "globally", whatever that means for your system (e.g. two instances of the same system could share a Redis cache if they have distinct keys).

Example:

```
@Bean
@ExportMetricWriter
MetricWriter metricWriter(MetricExportProperties export) {
  return new RedisMetricRepository(connectionFactory,
        export.getRedis().getPrefix(), export.getRedis().getKey());
  }
```

application.properties.

```
spring.metrics.export.redis.prefix: metrics.mysystem.${spring.application.name:application}.
${random.value:0000}
spring.metrics.export.redis.key: keys.metrics.mysystem
```

The prefix is constructed with the application name and id at the end, so it can easily be used to identify a group of processes with the same logical name later.

Note

It's important to set both the key and the prefix. The key is used for all repository operations, and can be shared by multiple repositories. If multiple repositories share a key (like in the case where you need to aggregate across them), then you normally have a read-only "master" repository that has a short, but identifiable, prefix (like "metrics.mysystem"), and many write-only repositories with prefixes that start with the master prefix (like metrics.mysystem.* in the example above). It is efficient to read all the keys from a "master" repository like that, but inefficient to read a subset with a longer prefix (e.g. using one of the writing repositories).

Tip

The example above uses MetricExportProperties to inject and extract the key and prefix. This is provided to you as a convenience by Spring Boot, configured with sensible defaults. There is nothing to stop you using your own values as long as they follow the recommendations.

Example: Export to Open TSDB

If you provide a <code>@Bean</code> of type <code>OpenTsdbGaugeWriter</code> and mark it <code>@ExportMetricWriter</code> metrics are exported to <u>Open TSDB</u> for aggregation. The <code>OpenTsdbGaugeWriter</code> has a url property that you need to set to the Open TSDB "/put" endpoint, e.g. <u>localhost:4242/api/put</u>). It also has a <code>namingStrategy</code> that you can customize or configure to make the metrics match the data structure you need on the server. By default it just passes through the metric name as an Open TSDB metric name, and adds the tags "domain" (with value "org.springframework.metrics") and "process" (with the value equal to the object hash of the naming strategy). Thus, after running the application and generating some metrics you can inspect the metrics in the TSD UI (<u>localhost:4242</u> by default).

Example:

```
"domain": "org.springframework.metrics",
"process": "b968a76"
},
"aggregateTags": [],
"dps": {
    "1430492872": 2,
    "1430492875": 6
}
]
```

Example: Export to Statsd

To export metrics to Statsd, make sure first that you have added com.timgroup:java-statsdclient as a dependency of your project (Spring Boot provides a dependency management for it). Then add a spring.metrics.export.statsd.host value to your application.properties file. Connections will be opened to port 8125 unless a spring.metrics.export.statsd.port override is provided. You can use spring.metrics.export.statsd.prefix if you want a custom prefix.

Alternatively, you can provide a @Bean of type StatsdMetricWriter and mark it @ExportMetricWriter:

```
@Value("${spring.application.name:application}.${random.value:0000}")
private String prefix = "metrics";

@Bean
@ExportMetricWriter
MetricWriter metricWriter() {
  return new StatsdMetricWriter(prefix, "localhost", "8125");
}
```

Example: Export to JMX

If you provide a @Bean of type JmxMetricWriter marked @ExportMetricWriter the metrics are exported as MBeans to the local server (the MBeanExporter is provided by Spring Boot JMX autoconfiguration as long as it is switched on). Metrics can then be inspected, graphed, alerted etc. using any tool that understands JMX (e.g. JConsole or JVisualVM).

Example:

```
@Bean
@ExportMetricWriter
MetricWriter metricWriter(MBeanExporter exporter) {
  return new JmxMetricWriter(exporter);
}
```

Each metric is exported as an individual MBean. The format for the ObjectNames is given by an ObjectNamingStrategy which can be injected into the JmxMetricWriter (the default breaks up the metric name and tags the first two period-separated sections in a way that should make the metrics group nicely in JVisualVM or JConsole).

49.9 Aggregating metrics from multiple sources

There is an AggregateMetricReader that you can use to consolidate metrics from different physical sources. Sources for the same logical metric just need to publish them with a period-separated prefix, and the reader will aggregate (by truncating the metric names, and dropping the prefix). Counters are summed and everything else (i.e. gauges) take their most recent value.

This is very useful if multiple application instances are feeding to a central (e.g. Redis) repository and you want to display the results. Particularly recommended in conjunction with a MetricReaderPublicMetrics for hooking up to the results to the "/metrics" endpoint.

Example:

```
@Autowired
private MetricExportProperties export;
@Bean
public PublicMetrics metricsAggregate() {
  return new MetricReaderPublicMetrics(aggregatesMetricReader());
}
private MetricReader globalMetricsForAggregation() {
  return new RedisMetricRepository(this.connectionFactory,
    this.export.getRedis().getAggregatePrefix(), this.export.getRedis().getKey());
}
private MetricReader aggregatesMetricReader() {
  AggregateMetricReader repository = new AggregateMetricReader(
    globalMetricsForAggregation());
  return repository;
}
```

Note

The example above uses MetricExportProperties to inject and extract the key and prefix. This is provided to you as a convenience by Spring Boot, and the defaults will be sensible. They are set up in MetricExportAutoConfiguration.

Note

The MetricReaders above are not @Beans and are not marked as @ExportMetricReader because they are just collecting and analyzing data from other repositories, and don't want to export their values.

49.10 Dropwizard Metrics

A default MetricRegistry Spring bean will be created when you declare a dependency to the io.dropwizard.metrics:metrics-core library; you can also register you own @Bean instance if you need customizations. Users of the <u>Dropwizard 'Metrics' library</u> will find that Spring Boot metrics are automatically published to com.codahale.metrics.MetricRegistry.Metrics from the MetricRegistry are also automatically exposed via the /metrics endpoint

When Dropwizard metrics are in use, the default CounterService and GaugeService are replaced with a DropwizardMetricServices, which is a wrapper around the MetricRegistry (so you can @Autowired one of those services and use it as normal). You can also create "special" Dropwizard metrics by prefixing your metric names with the appropriate type (i.e. timer.*, histogram.* for gauges, and meter.* for counters).

49.11 Message channel integration

If a MessageChannel bean called metricsChannel exists, then a MetricWriter will be created that writes metrics to that channel. The writer is automatically hooked up to an exporter (as for all writers), so all metric values will appear on the channel, and additional analysis or actions can be taken by subscribers (it's up to you to provide the channel and any subscribers you need).

50. Auditing

Spring Boot Actuator has a flexible audit framework that will publish events once Spring Security is in play ('authentication success', 'failure' and 'access denied' exceptions by default). This can be very useful for reporting, and also to implement a lock-out policy based on authentication failures. To customize published security events you can provide your own implementations of AbstractAuthenticationAuditListener and AbstractAuthorizationAuditListener.

You can also choose to use the audit services for your own business events. To do that you can either inject the existing AuditEventRepository into your own components and use that directly, or you can simply publish AuditApplicationEvent via the Spring ApplicationEventPublisher (using ApplicationEventPublisherAware).

51. Tracing

Tracing is automatically enabled for all HTTP requests. You can view the trace endpoint and obtain basic information about the last few requests:

```
[{
    "timestamp": 1394343677415,
    "info": {
     "method": "GET".
     "path": "/trace",
     "headers": {
        "request": {
          "Accept": "text/html,application/xhtml+xml,application/xml;q=0.9,*/*;q=0.8",
         "Connection": "keep-alive",
          "Accept-Encoding": "gzip, deflate",
          "User-Agent": "Mozilla/5.0 Gecko/Firefox",
          "Accept-Language": "en-US,en;q=0.5",
         "Cookie": "_ga=GA1.1.827067509.1390890128; ..."
          "Authorization": "Basic ....",
          "Host": "localhost:8080"
        },
        "response": {
          "Strict-Transport-Security": "max-age=31536000 ; includeSubDomains",
          "X-Application-Context": "application:8080",
          "Content-Type": "application/json;charset=UTF-8",
          "status": "200"
       }
     }
   3
  },{
    "timestamp": 1394343684465,
    . . .
    }1
```

51.1 Custom tracing

If you need to trace additional events you can inject a <u>TraceRepository</u> into your Spring beans. The add method accepts a single Map structure that will be converted to JSON and logged.

By default an InMemoryTraceRepository will be used that stores the last 100 events. You can define your own instance of the InMemoryTraceRepository bean if you need to expand the capacity. You can also create your own alternative TraceRepository implementation if needed.

52. Process monitoring

In Spring Boot Actuator you can find a couple of classes to create files that are useful for process monitoring:

- ApplicationPidFileWriter creates a file containing the application PID (by default in the application directory with the file name application.pid).
- EmbeddedServerPortFileWriter creates a file (or files) containing the ports of the embedded server (by default in the application directory with the file name application.port).

These writers are not activated by default, but you can enable them in one of the ways described below.

52.1 Extend configuration

In META-INF/spring.factories file you can activate the listener(s) that writes a PID file. Example:

```
org.springframework.context.ApplicationListener=\
```

```
org.springframework.boot.actuate.system.ApplicationPidFileWriter,
```

```
org.springframework.boot.actuate.system.EmbeddedServerPortFileWriter
```

52.2 Programmatically

You can also activate a listener by invoking the SpringApplication.addListeners(...) method and passing the appropriate Writer object. This method also allows you to customize the file name and path via the Writer constructor.

53. What to read next

If you want to explore some of the concepts discussed in this chapter, you can take a look at the actuator <u>sample applications</u>. You also might want to read about graphing tools such as <u>Graphite</u>.

Otherwise, you can continue on, to read about <u>'deployment options'</u> or jump ahead for some in-depth information about Spring Boot's *build tool plugins*.

Part VI. Deploying Spring Boot applications

Spring Boot's flexible packaging options provide a great deal of choice when it comes to deploying your application. You can easily deploy Spring Boot applications to a variety of cloud platforms, to a container images (such as Docker) or to virtual/real machines.

This section covers some of the more common deployment scenarios.

54. Deploying to the cloud

Spring Boot's executable jars are ready-made for most popular cloud PaaS (platform-as-a-service) providers. These providers tend to require that you "bring your own container"; they manage application processes (not Java applications specifically), so they need some intermediary layer that adapts *your* application to the *cloud's* notion of a running process.

Two popular cloud providers, Heroku and Cloud Foundry, employ a "buildpack" approach. The buildpack wraps your deployed code in whatever is needed to *start* your application: it might be a JDK and a call to java, it might be an embedded web server, or it might be a full-fledged application server. A buildpack is pluggable, but ideally you should be able to get by with as few customizations to it as possible. This reduces the footprint of functionality that is not under your control. It minimizes divergence between development and production environments.

Ideally, your application, like a Spring Boot executable jar, has everything that it needs to run packaged within it.

In this section we'll look at what it takes to get the <u>simple application that we developed</u> in the "Getting Started" section up and running in the Cloud.

54.1 Cloud Foundry

Cloud Foundry provides default buildpacks that come into play if no other buildpack is specified. The Cloud Foundry <u>Java buildpack</u> has excellent support for Spring applications, including Spring Boot. You can deploy stand-alone executable jar applications, as well as traditional .war packaged applications.

Once you've built your application (using, for example, mvn clean package) and installed the cf command line tool, simply deploy your application using the cf push command as follows, substituting the path to your compiled .jar. Be sure to have logged in with your cf command line client before pushing an application.

\$ cf push acloudyspringtime -p target/demo-0.0.1-SNAPSHOT.jar

See the <u>cf</u> <u>push</u> <u>documentation</u> for more options. If there is a Cloud Foundry <u>manifest.yml</u> file present in the same directory, it will be consulted.

Note

Here we are substituting acloudyspringtime for whatever value you give cf as the name of your application.

At this point cf will start uploading your application:

```
l of l instances running (l running)
App started
```

Congratulations! The application is now live!

It's easy to then verify the status of the deployed application:

```
$ cf apps
Getting applications in ...
OK
name requested state instances memory disk urls
...
acloudyspringtime started 1/1 512M 1G acloudyspringtime.cfapps.io
...
```

Once Cloud Foundry acknowledges that your application has been deployed, you should be able to hit the application at the URI given, in this case <u>acloudyspringtime.cfapps.io/</u>.

Binding to services

By default, metadata about the running application as well as service connection information is exposed to the application as environment variables (for example: \$VCAP_SERVICES). This architecture decision is due to Cloud Foundry's polyglot (any language and platform can be supported as a buildpack) nature; process-scoped environment variables are language agnostic.

Environment variables don't always make for the easiest API so Spring Boot automatically extracts them and flattens the data into properties that can be accessed through Spring's Environment abstraction:

```
@Component
class MyBean implements EnvironmentAware {
    private String instanceId;
    @Override
    public void setEnvironment(Environment environment) {
        this.instanceId = environment.getProperty("vcap.application.instance_id");
    }
    // ...
}
```

All Cloud Foundry properties are prefixed with vcap. You can use vcap properties to access application information (such as the public URL of the application) and service information (such as database credentials). See VcapApplicationListener Javadoc for complete details.

Тір

The <u>Spring Cloud Connectors</u> project is a better fit for tasks such as configuring a DataSource. Spring Boot includes auto-configuration support and a spring-boot-starter-cloudconnectors starter POM.

54.2 Heroku

Heroku is another popular PaaS platform. To customize Heroku builds, you provide a Procfile, which provides the incantation required to deploy an application. Heroku assigns a port for the Java application to use and then ensures that routing to the external URI works.

You must configure your application to listen on the correct port. Here's the Procfile for our starter REST application:

web: java -Dserver.port=\$PORT -jar target/demo-0.0.1-SNAPSHOT.jar

Spring Boot makes -D arguments available as properties accessible from a Spring Environment instance. The server.port configuration property is fed to the embedded Tomcat, Jetty or Undertow instance which then uses it when it starts up. The \$PORT environment variable is assigned to us by the Heroku PaaS.

Heroku by default will use Java 1.8. This is fine as long as your Maven or Gradle build is set to use the same version (Maven users can use the java.version property). If you want to use JDK 1.7, create a new file adjacent to your pom.xml and Procfile, called system.properties. In this file add the following:

```
java.runtime.version=1.7
```

This should be everything you need. The most common workflow for Heroku deployments is to git push the code to production.

```
$ git push heroku master
Initializing repository, done.
Counting objects: 95, done.
Delta compression using up to 8 threads.
Compressing objects: 100% (78/78), done.

```

Your application should now be up and running on Heroku.

54.3 OpenShift

<u>OpenShift</u> is the RedHat public (and enterprise) PaaS solution. Like Heroku, it works by running scripts triggered by git commits, so you can script the launching of a Spring Boot application in pretty much any way you like as long as the Java runtime is available (which is a standard feature you can ask for at OpenShift). To do this you can use the <u>DIY Cartridge</u> and hooks in your repository under .openshift/ action_scripts:

The basic model is to:

- 1. Ensure Java and your build tool are installed remotely, e.g. using a pre_build hook (Java and Maven are installed by default, Gradle is not)
- 2. Use a build hook to build your jar (using Maven or Gradle), e.g.

```
#!/bin/bash
cd $OPENSHIFT_REPO_DIR
mvn package -s .openshift/settings.xml -DskipTests=true
```

3. Add a start hook that calls java -jar ...

```
#!/bin/bash
cd $OPENSHIFT_REPO_DIR
nohup java -jar target/*.jar --server.port=${OPENSHIFT_DIY_PORT} --server.address=${OPENSHIFT_DIY_IP}
&
```

4. Use a stop hook (since the start is supposed to return cleanly), e.g.

5. Embed service bindings from environment variables provided by the platform in your application.properties, e.g.

```
spring.datasource.url: jdbc:mysql://${OPENSHIFT_MYSQL_DB_HOST}:${OPENSHIFT_MYSQL_DB_PORT}/
${OPENSHIFT_APP_NAME}
spring.datasource.username: ${OPENSHIFT_MYSQL_DB_USERNAME}
spring.datasource.password: ${OPENSHIFT_MYSQL_DB_PASSWORD}
```

There's a blog on <u>running Gradle in OpenShift</u> on their website that will get you started with a gradle build to run the app.

54.4 Boxfuse and Amazon Web Services

<u>Boxfuse</u> works by turning your Spring Boot executable jar or war into a minimal VM image that can be deployed unchanged either on VirtualBox or on AWS. Boxfuse comes with deep integration for Spring Boot and will use the information from your Spring Boot configuration file to automatically configure ports and health check URLs. Boxfuse leverages this information both for the images it produces as well as for all the resources it provisions (instances, security groups, elastic load balancers, etc).

Once you have created a <u>Boxfuse account</u>, connected it to your AWS account, and installed the latest version of the Boxfuse Client, you can deploy your Spring Boot application to AWS as follows (ensure the application has been built by Maven or Gradle first using, for example, mvn clean package):

\$ boxfuse run myapp-1.0.jar -env=prod

See the <u>boxfuse run</u> documentation for more options. If there is a <u>boxfuse.com/docs/commandline/</u> <u>#configuration</u> [boxfuse.conf] file present in the current directory, it will be consulted.

Тір

By default Boxfuse will activate a Spring profile named boxfuse on startup and if your executable jar or war contains an <u>boxfuse.com/docs/payloads/springboot.html#configuration</u> [application-boxfuse.properties] file, Boxfuse will base its configuration based on the properties it contains.

At this point boxfuse will create an image for your application, upload it, and then configure and start the necessary resources on AWS:

```
Fusing Image for myapp-1.0.jar ...
Image fused in 00:06.838s (53937 K) -> axelfontaine/myapp:1.0
Creating axelfontaine/myapp ...
Pushing axelfontaine/myapp:1.0 ..
Verifying axelfontaine/myapp:1.0 ...
Creating Elastic IP ...
Mapping myapp-axelfontaine.boxfuse.io to 52.28.233.167 ...
Waiting for AWS to create an AMI for axelfontaine/myapp:1.0 in eu-central-1 (this may take up to 50
seconds) ..
AMI created in 00:23.557s -> ami-d23f38cf
Creating security group boxfuse-sg_axelfontaine/myapp:1.0
Launching t2.micro instance of axelfontaine/myapp:1.0 (ami-d23f38cf) in eu-central-1 ...
Instance launched in 00:30.306s -> i-92ef9f53
Waiting for AWS to boot Instance i-92ef9f53 and Payload to start at http://52.28.235.61/ ...
Payload started in 00:29.266s -> http://52.28.235.61/
Remapping Elastic IP 52.28.233.167 to i-92ef9f53 ...
Waiting 15s for AWS to complete Elastic IP Zero Downtime transition ...
Deployment completed successfully. axelfontaine/myapp:1.0 is up and running at http://myapp-
axelfontaine.boxfuse.io/
```

Your application should now be up and running on AWS.

There's a blog on <u>deploying Spring Boot apps on EC2</u> as well as <u>documentation for the Boxfuse Spring</u> <u>Boot integration</u> on their website that will get you started with a Maven build to run the app.

54.5 Google App Engine

Google App Engine is tied to the Servlet 2.5 API, so you can't deploy a Spring Application there without some modifications. See the <u>Servlet 2.5 section</u> of this guide.

55. Installing Spring Boot applications

In additional to running Spring Boot applications using java -jar it is also possible to make fully executable applications for Unix systems (Linux, OSX, FreeBSD etc). This makes it very easy to install and manage Spring Boot applications in common production environments. As long as you are generating 'fully executable' jars from your build, and you are not using a custom embeddedLaunchScript, the following techniques can be used.

To create a 'fully executable' jar with Maven use the following plugin configuration:

```
<plugin>
<groupId>org.springframework.boot</groupId>
<artifactId>spring-boot-maven-plugin</artifactId>
<configuration>
</configuration>
</plugin>
```

With Gradle, the equivalent configuration would be:

```
apply plugin: 'spring-boot'
springBoot {
    executable = true
}
```

Note

Fully executable jars work by embedding an extra script at the front of the file. Not all tools currently accept this format so you may not always be able to use this technique.

Note

When a fully executable jar is run, it uses the jar's directory as the working directory.

55.1 Unix/Linux services

Spring Boot application can be easily started as Unix/Linux services using either init.d or systemd.

Installation as an init.d service (System V)

The default executable script that can be embedded into Spring Boot jars will act as an init.d script when it is symlinked to /etc/init.d. The standard start, stop, restart and status commands can be used. The script supports the following features:

- Starts the services as the user that owns the jar file
- Tracks application's PID using /var/run/<appname>/<appname>.pid
- Writes console logs to /var/log/<appname>.log

Assuming that you have a Spring Boot application installed in /var/myapp, to install a Spring Boot application as an init.d service simply create a symlink:

```
$ sudo ln -s /var/myapp/myapp.jar /etc/init.d/myapp
```

Once installed, you can start and stop the service in the usual way. You can also flag the application to start automatically using your standard operating system tools. For example, if you use Debian:

```
$ update-rc.d myapp defaults <priority>
```

Securing an init.d service

Note

The following is a set of guidelines on how to secure a Spring Boot application that's being run as an init.d service. It is not intended to be an exhaustive list of everything that should be done to harden an application and the environment in which it runs.

When executed as root, as is the case when root is being used to start an init.d service, the default executable script will run the application as the user which owns the jar file. You should never run a Spring Boot application as root so your application's jar file should never be owned by root. Instead, create a specific user to run your application and use chown to make it the owner of the jar file. For example:

\$ chown bootapp:bootapp your-app.jar

In this case, the default executable script will run the application as the bootapp user.

Tip

To reduce the chances of the application's user account being compromised, you should consider preventing it from using a login shell. Set the account's shell to /usr/sbin/nologin, for example.

You should also take steps to prevent the modification of your application's jar file. Firstly, configure its permissions so that it cannot be written and can only be read or executed by its owner:

```
$ chmod 500 your-app.jar
```

Secondly, you should also take steps to limit the damage if your application or the account that's running it is compromised. If an attacker does gain access, they could make the jar file writable and change its contents. One way to protect against this is to make it immutable using chattr:

\$ sudo chattr +i your-app.jar

This will prevent any user, including root, from modifying the jar.

If root is used to control the application's service and you <u>use a .conf file</u> to customize its startup, the .conf file will be read and evaluated by the root user. It should be secured accordingly. Use chmod so that the file can only be read by the owner and use chown to make root the owner:

```
$ chmod 400 your-app.conf
$ sudo chown root:root your-app.conf
```

Installation as a systemd service

Systemd is the successor of the System V init system, and is now being used by many modern Linux distributions. Although you can continue to use init.d scripts with systemd, it is also possible to launch Spring Boot applications using systemd 'service' scripts.

Assuming that you have a Spring Boot application installed in /var/myapp, to install a Spring Boot application as a systemd service create a script named myapp.service using the following example and place it in /etc/systemd/system directory:

```
[Unit]
Description=myapp
After=syslog.target
[Service]
User=myapp
ExecStart=/var/myapp/myapp.jar
SuccessExitStatus=143
[Install]
WantedBy=multi-user.target
```

Тір

Remember to change the Description, User and ExecStart fields for your application.

Note that unlike when running as an init.d service, user that runs the application, PID file and console log file behave differently under systemd and must be configured using appropriate fields in 'service' script. Consult the service unit configuration man page for more details.

To flag the application to start automatically on system boot use the following command:

\$ systemctl enable myapp.service

Refer to man systemctl for more details.

Customizing the startup script

The script accepts the following parameters as environment variables, so you can change the default behavior in a script or on the command line:

Variable	Description
MODE	The "mode" of operation. The default depends on the way the jar was built, but will usually be auto (meaning it tries to guess if it is an init script by checking if it is a symlink in a directory called init.d). You can explicitly set it to service so that the stop start status restart commands work, or to run if you just want to run the script in the foreground.
USE_START_	ട്രിൻ എക്ഷാസ്സെടtop-daemon command, when it's available, should be used to control the process. Defaults to true.
PID_FOLDER	The root name of the pid folder (/var/run by default).
LOG_FOLDER	The name of the folder to put log files in (/var/log by default).
LOG_FILENA	MEHE name of the log file in the LOG_FOLDER (<appname>.log by default).</appname>
APP_NAME	The name of the app. If the jar is run from a symlink the script guesses the app name, but if it is not a symlink, or you want to explicitly set the app name this can be useful.
RUN_ARGS	The arguments to pass to the program (the Spring Boot app).

Variable	Description
JAVA_HOME	The location of the java executable is discovered by using the PATH by default, but you can set it explicitly if there is an executable file at $JAVA_HOME/bin/java$.
JAVA_OPTS	Options that are passed to the JVM when it is launched.
JARFILE	The explicit location of the jar file, in case the script is being used to launch a jar that it is not actually embedded in.
DEBUG	if not empty will set the $-x$ flag on the shell process, making it easy to see the logic in the script.

Note

The PID_FOLDER, LOG_FOLDER and LOG_FILENAME variables are only valid for an init.d service. With systemd the equivalent customizations are made using 'service' script. Check the service unit configuration man page for more details.

In addition, the following properties can be changed when the script is written by using the embeddedLaunchScriptProperties option of the Spring Boot Maven or Gradle plugins.

Name	Description
mode	The script mode. Defaults to auto.
initInfoPr	oThiclesovides section of "INIT INFO". Defaults to spring-boot-application for Gradle and to \${project.artifactId} for Maven.
initInfoSh	oThe ShortpDescription section of "INIT INFO". Defaults to Spring Boot Application for Gradle and to \${project.name} for Maven.
initInfoDe	sThepesoniption section of "INIT INFO". Defaults to Spring Boot Application for Gradle and to \${project.description} (falling back to \${project.name}) for Maven.
initInfoCh	k Hue nthing config section of "INIT INFO". Defaults to 2345 99 01.
useStartSt	dptheesetart-stop-daemon command, when it's available, should be used to control the process. Defaults to true.

Customizing the startup script with a conf file

With the exception of JARFILE and APP_NAME, the above settings can be configured using a . conf file,

```
JAVA_OPTS=-Xmx1024M
LOG_FOLDER=/custom/log/folder
```

The file should be situated next to the jar file and have the same name but suffixed with .conf rather than .jar. For example, a jar named /var/myapp/myapp.jar will use the configuration file named /var/myapp/myapp.conf if it exists.

To learn about securing this file appropriately, please refer to the guidelines for securing an init.d service.

56. Microsoft Windows services

Spring Boot application can be started as Windows service using <u>winsw</u>.

A sample <u>maintained separately</u> to the core of Spring Boot describes step-by-step how you can create a Windows service for your Spring Boot application.

57. What to read next

Check out the <u>Cloud Foundry</u>, <u>Heroku</u>, <u>OpenShift</u> and <u>Boxfuse</u> web sites for more information about the kinds of features that a PaaS can offer. These are just four of the most popular Java PaaS providers, since Spring Boot is so amenable to cloud-based deployment you're free to consider other providers as well.

The next section goes on to cover the <u>Spring Boot CLI</u>; or you can jump ahead to read about <u>build</u> <u>tool plugins</u>.

Part VII. Spring Boot CLI

The Spring Boot CLI is a command line tool that can be used if you want to quickly develop with Spring. It allows you to run Groovy scripts, which means that you have a familiar Java-like syntax, without so much boilerplate code. You can also bootstrap a new project or write your own command for it.

58. Installing the CLI

The Spring Boot CLI can be installed manually; using SDKMAN! (the SDK Manager) or using Homebrew or MacPorts if you are an OSX user. See <u>Section 10.2</u>, <u>"Installing the Spring Boot CLI"</u> in the "Getting started" section for comprehensive installation instructions.

59. Using the CLI

Once you have installed the CLI you can run it by typing spring. If you run spring without any arguments, a simple help screen is displayed:

You can use help to get more details about any of the supported commands. For example:

The version command provides a quick way to check which version of Spring Boot you are using.

```
$ spring version
Spring CLI v1.3.3.RELEASE
```

59.1 Running applications using the CLI

You can compile and run Groovy source code using the run command. The Spring Boot CLI is completely self-contained so you don't need any external Groovy installation.

Here is an example "hello world" web application written in Groovy:

hello.groovy.

```
@RestController
class WebApplication {
    @RequestMapping("/")
    String home() {
        "Hello World!"
    }
}
```

To compile and run the application type:

```
$ spring run hello.groovy
```

To pass command line arguments to the application, you need to use a -- to separate them from the "spring" command arguments, e.g.

\$ spring run hello.groovy -- --server.port=9000

To set JVM command line arguments you can use the JAVA_OPTS environment variable, e.g.

\$ JAVA_OPTS=-Xmx1024m spring run hello.groovy

Deduced "grab" dependencies

Standard Groovy includes a @Grab annotation which allows you to declare dependencies on a thirdparty libraries. This useful technique allows Groovy to download jars in the same way as Maven or Gradle would, but without requiring you to use a build tool.

Spring Boot extends this technique further, and will attempt to deduce which libraries to "grab" based on your code. For example, since the WebApplication code above uses @RestController annotations, "Tomcat" and "Spring MVC" will be grabbed.

The following items are used as "grab hints":

Items	Grabs
JdbcTemplate, NamedParameterJdbcTemplate, DataSource	JDBC Application.
@EnableJms	JMS Application.
<pre>@EnableCaching</pre>	Caching abstraction.
@Test	JUnit.
@EnableRabbit	RabbitMQ.
@EnableReactor	Project Reactor.
extends Specification	Spock test.
<pre>@EnableBatchProcessing</pre>	Spring Batch.
<pre>@MessageEndpoint @EnableIntegrationPatterns</pre>	Spring Integration.
<pre>@EnableDeviceResolver</pre>	Spring Mobile.
@Controller @RestController @EnableWebMvc	Spring MVC + Embedded Tomcat.
@EnableWebSecurity	Spring Security.
@EnableTransactionManagement	Spring Transaction Management.

Тір

See subclasses of <u>CompilerAutoConfiguration</u> in the Spring Boot CLI source code to understand exactly how customizations are applied.

Deduced "grab" coordinates

Spring Boot extends Groovy's standard @Grab support by allowing you to specify a dependency without a group or version, for example @Grab('freemarker'). This will consult Spring Boot's default dependency metadata to deduce the artifact's group and version. Note that the default metadata is tied to the version of the CLI that you're using – it will only change when you move to a new version of the CLI, putting you in control of when the versions of your dependencies may change. A table showing the dependencies and their versions that are included in the default metadata can be found in the <u>appendix</u>.

Default import statements

To help reduce the size of your Groovy code, several import statements are automatically included. Notice how the example above refers to @Component, @RestController and @RequestMapping without needing to use fully-qualified names or import statements.

Тір

Many Spring annotations will work without using import statements. Try running your application to see what fails before adding imports.

Automatic main method

Unlike the equivalent Java application, you do not need to include a public static void main(String[] args) method with your Groovy scripts. A SpringApplication is automatically created, with your compiled code acting as the source.

Custom dependency management

By default, the CLI uses the dependency management declared in spring-boot-dependencies when resolving @Grab dependencies. Additional dependency management, that will override the default dependency management, can be configured using the @DependencyManagementBom annotation. The annotation's value should specify the coordinates (groupId:artifactId:version) of one or more Maven BOMs.

For example, the following declaration:

@DependencyManagementBom("com.example.custom-bom:1.0.0")

Will pick up custom-bom-1.0.0.pom in a Maven repository under com/example/custom-versions/1.0.0/.

When multiple BOMs are specified they are applied in the order that they're declared. For example:

indicates that dependency management in another-bom will override the dependency management in custom-bom.

You can use @DependencyManagementBom anywhere that you can use @Grab, however, to ensure consistent ordering of the dependency management, you can only use @DependencyManagementBom at most once in your application. A useful source of dependency management (that is

a superset of Spring Boot's dependency management) is the <u>Spring IO Platform</u>, e.g. @DependencyManagementBom('io.spring.platform:platform-bom:1.1.2.RELEASE').

59.2 Testing your code

The test command allows you to compile and run tests for your application. Typical usage looks like this:

```
$ spring test app.groovy tests.groovy
Total: 1, Success: 1, : Failures: 0
Passed? true
```

In this example, tests.groovy contains JUnit @Test methods or Spock Specification classes. All the common framework annotations and static methods should be available to you without having to import them.

Here is the tests.groovy file that we used above (with a JUnit test):

```
class ApplicationTests {
    @Test
    void homeSaysHello() {
        assertEquals("Hello World!", new WebApplication().home())
    }
}
```

Тір

If you have more than one test source files, you might prefer to organize them into a test directory.

59.3 Applications with multiple source files

You can use "shell globbing" with all commands that accept file input. This allows you to easily use multiple files from a single directory, e.g.

\$ spring run *.groovy

This technique can also be useful if you want to segregate your "test" or "spec" code from the main application code:

\$ spring test app/*.groovy test/*.groovy

59.4 Packaging your application

You can use the jar command to package your application into a self-contained executable jar file. For example:

\$ spring jar my-app.jar *.groovy

The resulting jar will contain the classes produced by compiling the application and all of the application's dependencies so that it can then be run using java -jar. The jar file will also contain entries from the application's classpath. You can add explicit paths to the jar using --include and --exclude (both are comma-separated, and both accept prefixes to the values "+" and "-" to signify that they should be removed from the defaults). The default includes are

public/**, resources/**, static/**, templates/**, META-INF/**, *

and the default excludes are

```
.*, repository/**, build/**, target/**, **/*.jar, **/*.groovy
```

See the output of spring help jar for more information.

59.5 Initialize a new project

The init command allows you to create a new project using <u>start.spring.io</u> without leaving the shell. For example:

```
$ spring init --dependencies=web,data-jpa my-project
Using service at https://start.spring.io
Project extracted to '/Users/developer/example/my-project'
```

This creates a my-project directory with a Maven-based project using spring-boot-starterweb and spring-boot-starter-data-jpa. You can list the capabilities of the service using the -list flag

The init command supports many options, check the help output for more details. For instance, the following command creates a gradle project using Java 8 and war packaging:

```
$ spring init --build=gradle --java-version=1.8 --dependencies=websocket --packaging=war sample-app.zip
Using service at https://start.spring.io
Content saved to 'sample-app.zip'
```

59.6 Using the embedded shell

Spring Boot includes command-line completion scripts for BASH and zsh shells. If you don't use either of these shells (perhaps you are a Windows user) then you can use the shell command to launch an integrated shell.

```
$ spring shell
Spring Boot (v1.3.3.RELEASE)
Hit TAB to complete. Type \'help' and hit RETURN for help, and \'exit' to quit.
```

From inside the embedded shell you can run other commands directly:

```
$ version
Spring CLI v1.3.3.RELEASE
```

The embedded shell supports ANSI color output as well as tab completion. If you need to run a native command you can use the \$ prefix. Hitting ctrl-c will exit the embedded shell.

59.7 Adding extensions to the CLI

You can add extensions to the CLI using the install command. The command takes one or more sets of artifact coordinates in the format group:artifact:version. For example:

\$ spring install com.example:spring-boot-cli-extension:1.0.0.RELEASE

In addition to installing the artifacts identified by the coordinates you supply, all of the artifacts' dependencies will also be installed.

To uninstall a dependency use the uninstall command. As with the install command, it takes one or more sets of artifact coordinates in the format group:artifact:version. For example:

\$ spring uninstall com.example:spring-boot-cli-extension:1.0.0.RELEASE

It will uninstall the artifacts identified by the coordinates you supply and their dependencies.

To uninstall all additional dependencies you can use the --all option. For example:

\$ spring uninstall --all

60. Developing application with the Groovy beans DSL

Spring Framework 4.0 has native support for a beans { } "DSL" (borrowed from <u>Grails</u>), and you can embed bean definitions in your Groovy application scripts using the same format. This is sometimes a good way to include external features like middleware declarations. For example:

You can mix class declarations with beans { } in the same file as long as they stay at the top level, or you can put the beans DSL in a separate file if you prefer.

61. Configuring the CLI with settings.xml

The Spring Boot CLI uses Aether, Maven's dependency resolution engine, to resolve dependencies. The CLI makes use of the Maven configuration found in $\sim/.m2/settings.xml$ to configure Aether. The following configuration settings are honored by the CLI:

- Offline
- Mirrors
- Servers
- Proxies
- Profiles
 - Activation
 - Repositories
- Active profiles

Please refer to <u>Maven's settings documentation</u> for further information.

62. What to read next

There are some <u>sample groovy scripts</u> available from the GitHub repository that you can use to try out the Spring Boot CLI. There is also extensive javadoc throughout the <u>source code</u>.

If you find that you reach the limit of the CLI tool, you will probably want to look at converting your application to full Gradle or Maven built "groovy project". The next section covers Spring Boot's <u>Build</u> <u>tool plugins</u> that you can use with Gradle or Maven.

Part VIII. Build tool plugins

Spring Boot provides build tool plugins for Maven and Gradle. The plugins offer a variety of features, including the packaging of executable jars. This section provides more details on both plugins, as well as some help should you need to extend an unsupported build system. If you are just getting started, you might want to read "Chapter 13, *Build systems*" from the Part III, "Using Spring Boot" section first.

63. Spring Boot Maven plugin

The <u>Spring Boot Maven Plugin</u> provides Spring Boot support in Maven, allowing you to package executable jar or war archives and run an application "in-place". To use it you must be using Maven 3.2 (or better).

Note

Refer to the Spring Boot Maven Plugin Site for complete plugin documentation.

63.1 Including the plugin

To use the Spring Boot Maven Plugin simply include the appropriate XML in the plugins section of your pom.xml

```
<?xml version="1.0" encoding="UTF-8"?>
yroject xmlns="http://maven.apache.org/POM/4.0.0" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation="http://maven.apache.org/POM/4.0.0 http://maven.apache.org/xsd/maven-4.0.0.xsd">
   <modelVersion>4.0.0</modelVersion>
   <!-- ...
   <build>
       <plugins>
           <plugin>
               <groupId>org.springframework.boot</groupId>
               <artifactId>spring-boot-maven-plugin</artifactId>
               <version>1.3.3.RELEASE</version>
                <executions>
                    <execution>
                        <goals>
                           <goal>repackage</goal>
                        </goals>
                    </execution>
               </executions>
           </plugin>
        </plugins>
   </build>
</project>
```

This configuration will repackage a jar or war that is built during the package phase of the Maven lifecycle. The following example shows both the repackaged jar, as well as the original jar, in the target directory:

```
$ mvn package
$ ls target/*.jar
target/myproject-1.0.0.jar target/myproject-1.0.0.jar.original
```

If you don't include the <execution/> configuration as above, you can run the plugin on its own (but only if the package goal is used as well). For example:

```
$ mvn package spring-boot:repackage
$ ls target/*.jar
target/myproject-1.0.0.jar target/myproject-1.0.0.jar.original
```

If you are using a milestone or snapshot release you will also need to add appropriate pluginRepository elements:

```
<pluginRepositories>
<pluginRepository>
<id>spring-snapshots</id>
<url>http://repo.spring.io/snapshot</url>
```

```
</pluginRepository>
<pluginRepository>
<id>spring-milestones</id>
<url>http://repo.spring.io/milestone</url>
</pluginRepository>
</pluginRepositories>
```

63.2 Packaging executable jar and war files

Once spring-boot-maven-plugin has been included in your pom.xml it will automatically attempt
to rewrite archives to make them executable using the spring-boot:repackage goal. You should
configure your project to build a jar or war (as appropriate) using the usual packaging element:

```
<?xml version="1.0" encoding="UTF-8"?>
<project xmlns="http://maven.apache.org/POM/4.0.0" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://maven.apache.org/POM/4.0.0 http://maven.apache.org/xsd/maven-4.0.0.xsd">
    </project xmlns="http://maven.apache.org/POM/4.0.0" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://maven.apache.org/POM/4.0.0 http://maven.apache.org/xsd/maven-4.0.0.xsd">
    </project xmlns="http://maven.apache.org/POM/4.0.0" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://maven.apache.org/POM/4.0.0 http://maven.apache.org/xsd/maven-4.0.0.xsd">
```

Your existing archive will be enhanced by Spring Boot during the package phase. The main class that you want to launch can either be specified using a configuration option, or by adding a Main-Class attribute to the manifest in the usual way. If you don't specify a main class the plugin will search for a class with a public static void main(String[] args) method.

To build and run a project artifact, you can type the following:

```
$ mvn package
$ java -jar target/mymodule-0.0.1-SNAPSHOT.jar
```

To build a war file that is both executable and deployable into an external container you need to mark the embedded container dependencies as "provided", e.g:

Тір

See the "Section 80.1, "Create a deployable war file"" section for more details on how to create a deployable war file.

Advanced configuration options and examples are available in the plugin info page.

64. Spring Boot Gradle plugin

The Spring Boot Gradle Plugin provides Spring Boot support in Gradle, allowing you to package executable jar or war archives, run Spring Boot applications and use the dependency management provided by spring-boot-dependencies.

64.1 Including the plugin

To use the Spring Boot Gradle Plugin simply include a buildscript dependency and apply the spring-boot plugin:

```
buildscript {
    dependencies {
        classpath("org.springframework.boot:spring-boot-gradle-plugin:1.3.3.RELEASE")
    }
    apply plugin: 'spring-boot'
```

If you are using a milestone or snapshot release you will also need to add appropriate repositories reference:

```
buildscript {
   repositories {
      maven.url "http://repo.spring.io/snapshot"
      maven.url "http://repo.spring.io/milestone"
   }
   // ...
}
```

64.2 Gradle dependency management

The spring-boot plugin automatically applies the <u>Dependency Management Plugin</u> and configures in to import the spring-boot-starter-parent bom. This provides a similar dependency management experience to the one that is enjoyed by Maven users. For example, it allows you to omit version numbers when declaring dependencies that are managed in the bom. To make use of this functionality, simply declare dependencies in the usual way, but leave the version number empty:

```
dependencies {
    compile("org.springframework.boot:spring-boot-starter-web")
    compile("org.thymeleaf:thymeleaf-spring4")
    compile("nz.net.ultraq.thymeleaf:thymeleaf-layout-dialect")
}
```

Note

The version of the spring-boot gradle plugin that you declare determines the version of the spring-boot-starter-parent bom that is imported (this ensures that builds are always repeatable). You should always set the version of the spring-boot gradle plugin to the actual Spring Boot version that you wish to use. Details of the versions that are provided can be found in the <u>appendix</u>.

The dependency management plugin will only supply a version where one is not specified. To use a version of an artifact that differs from the one that the plugin would provide, simply specify the version when you declare the dependency as you usually would. For example:

```
dependencies {
```

```
compile("org.thymeleaf:thymeleaf-spring4:2.1.1.RELEASE")
```

To learn more about the capabilities of the Dependency Management Plugin, please refer to its documentation.

64.3 Packaging executable jar and war files

Once the spring-boot plugin has been applied to your project it will automatically attempt to rewrite archives to make them executable using the <u>bootRepackage task</u>. You should configure your project to build a jar or war (as appropriate) in the usual way.

The main class that you want to launch can either be specified using a configuration option, or by adding a Main-Class attribute to the manifest. If you don't specify a main class the plugin will search for a class with a public static void main(String[] args) method.

Тір

}

Check Section 64.6, "Repackage configuration" for a full list of configuration options.

To build and run a project artifact, you can type the following:

```
$ gradle build
$ java -jar build/libs/mymodule-0.0.1-SNAPSHOT.jar
```

To build a war file that is both executable and deployable into an external container, you need to mark the embedded container dependencies as belonging to a configuration named "providedRuntime", e.g.

```
. . .
apply plugin: 'war'
war {
   baseName = 'myapp'
    version = '0.5.0'
}
repositories {
    jcenter()
    maven { url "http://repo.spring.io/libs-snapshot" }
}
configurations {
   providedRuntime
}
dependencies {
    compile("org.springframework.boot:spring-boot-starter-web")
    providedRuntime("org.springframework.boot:spring-boot-starter-tomcat")
}
```

Tip

See the "<u>Section 80.1, "Create a deployable war file</u>"" section for more details on how to create a deployable war file.

64.4 Running a project in-place

To run a project in place without building a jar first you can use the "bootRun" task:

\$ gradle bootRun

If <u>devtools</u> has been added to your project it will automatically monitor your application for changes. Alternatively, you can also run the application so that your static classpath resources (i.e. in <u>src/main/</u>resources by default) are reloadable in the live application, which can be helpful at development time.

```
bootRun {
    addResources = true
}
```

Making static classpath resources reloadable means that bootRun does not use the output of the processResources task, i.e., when invoked using bootRun, your application will use the resources in their unprocessed form.

64.5 Spring Boot plugin configuration

The gradle plugin automatically extends your build script DSL with a springBoot element for global configuration of the Boot plugin. Set the appropriate properties as you would with any other Gradle extension (see below for a list of configuration options):

```
springBoot {
    backupSource = false
}
```

64.6 Repackage configuration

The plugin adds a bootRepackage task which you can also configure directly, e.g.:

```
bootRepackage {
    mainClass = 'demo.Application'
}
```

The following configuration options are available:

Name	Description
enabled	Boolean flag to switch the repackager off (sometimes useful if you want the other Boot features but not this one)
mainClass	The main class that should be run. If not specified, and you have applied the application plugin, the mainClassName project property will be used. If the application plugin has not been applied or no mainClassName has been specified, the archive will be searched for a suitable class. "Suitable" means a unique class with a well-formed main() method (if more than one is found the build will fail). If you have applied the application plugin, the main class can also be specified via its "run" task (main property) and/or its "startScripts" task (mainClassName property) as an alternative to using the "springBoot" configuration.
classifier	A file name segment (before the extension) to add to the archive, so that the original is preserved in its original location. Defaults to null in which case the archive is repackaged in place. The default is convenient for many purposes, but if you want to use

Name	Description
	the original jar as a dependency in another project, it's best to use an extension to define the executable archive.
withJarTask	The name or value of the $\tt Jar$ task (defaults to all tasks of type $\tt Jar$) which is used to locate the archive to repackage.
customConfiguration	The name of the custom configuration which is used to populate the nested lib directory (without specifying this you get all compile and runtime dependencies).
executable	Boolean flag to indicate if jar files are fully executable on Unix like operating systems. Defaults to false.
embeddedLaunchScript	The embedded launch script to prepend to the front of the jar if it is fully executable. If not specified the 'Spring Boot' default script will be used.
embeddedLaunchScriptProp	eAdditional properties that to be expanded in the launch script. The default script supports a mode property which can contain the values auto, service or run.
excludeDevtools	Boolean flag to indicate if the devtools jar should be excluded from the repackaged archives. Defaults to false.

64.7 Repackage with custom Gradle configuration

Sometimes it may be more appropriate to not package default dependencies resolved from compile, runtime and provided scopes. If the created executable jar file is intended to be run as it is, you need to have all dependencies nested inside it; however, if the plan is to explode a jar file and run the main class manually, you may already have some of the libraries available via CLASSPATH. This is a situation where you can repackage your jar with a different set of dependencies.

Using a custom configuration will automatically disable dependency resolving from compile, runtime and provided scopes. Custom configuration can be either defined globally (inside the springBoot section) or per task.

```
task clientJar(type: Jar) {
    appendix = 'client'
    from sourceSets.main.output
    exclude('**/*Something*')
}
task clientBoot(type: BootRepackage, dependsOn: clientJar) {
    withJarTask = clientJar
    customConfiguration = "mycustomconfiguration"
}
```

In above example, we created a new clientJar Jar task to package a customized file set from your compiled sources. Then we created a new clientBoot BootRepackage task and instructed it to work with only clientJar task and mycustomconfiguration.

```
configurations {
    mycustomconfiguration.exclude group: 'log4j'
}
dependencies {
```

```
mycustomconfiguration configurations.runtime
```

The configuration that we are referring to in BootRepackage is a normal <u>Gradle configuration</u>. In the above example we created a new configuration named mycustomconfiguration instructing it to derive from a runtime and exclude the log4j group. If the clientBoot task is executed, the repackaged boot jar will have all dependencies from runtime but no log4j jars.

Configuration options

}

The following configuration options are available:

Name	Description
mainClass	The main class that should be run by the executable archive.
providedConfiguration	The name of the provided configuration (defaults to providedRuntime).
backupSource	If the original source archive should be backed-up before being repackaged (defaults to true).
customConfiguration	The name of the custom configuration.
layout	The type of archive, corresponding to how the dependencies are laid out inside (defaults to a guess based on the archive type).
requiresUnpack	A list of dependencies (in the form "groupId:artifactId" that must be unpacked from fat jars in order to run. Items are still packaged into the fat jar, but they will be automatically unpacked when it runs.

64.8 Understanding how the Gradle plugin works

When spring-boot is applied to your Gradle project a default task named bootRepackage is created automatically. The bootRepackage task depends on Gradle assemble task, and when executed, it tries to find all jar artifacts whose qualifier is empty (i.e. tests and sources jars are automatically skipped).

Due to the fact that bootRepackage finds 'all' created jar artifacts, the order of Gradle task execution is important. Most projects only create a single jar file, so usually this is not an issue; however, if you are planning to create a more complex project setup, with custom Jar and BootRepackage tasks, there are few tweaks to consider.

If you are 'just' creating custom jar files from your project you can simply disable default jar and bootRepackage tasks:

```
jar.enabled = false
bootRepackage.enabled = false
```

Another option is to instruct the default bootRepackage task to only work with a default jar task.

bootRepackage.withJarTask = jar

If you have a default project setup where the main jar file is created and repackaged, 'and' you still want to create additional custom jars, you can combine your custom repackage tasks together and use dependsOn so that the bootJars task will run after the default bootRepackage task is executed:

```
task bootJars
bootJars.dependsOn = [clientBoot1,clientBoot2,clientBoot3]
build.dependsOn(bootJars)
```

All the above tweaks are usually used to avoid situations where an already created boot jar is repackaged again. Repackaging an existing boot jar will not break anything, but you may find that it includes unnecessary dependencies.

64.9 Publishing artifacts to a Maven repository using Gradle

If you are <u>declaring dependencies without versions</u> and you want to publish artifacts to a Maven repository you will need to configure the Maven publication with details of Spring Boot's dependency management. This can be achieved by configuring it to publish poms that inherit from spring-bootstarter-parent or that import dependency management from spring-boot-dependencies. The exact details of this configuration depend on how you're using Gradle and how you're trying to publish the artifacts.

Configuring Gradle to produce a pom that inherits dependency management

The following is an example of configuring Gradle to generate a pom that inherits from spring-bootstarter-parent. Please refer to the <u>Gradle User Guide</u> for further information.

Configuring Gradle to produce a pom that imports dependency management

The following is an example of configuring Gradle to generate a pom that imports the dependency management provided by spring-boot-dependencies. Please refer to the <u>Gradle User Guide</u> for further information.

	}
}	
}	
}	
}	
}	
}	

65. Spring Boot AntLib module

The Spring Boot AntLib module provides basic Spring Boot support for Apache Ant. You can use the module to create executable jars. To use the module you need to declare an additional spring-boot namespace in your build.xml:

You'll need to remember to start Ant using the -lib option, for example:

\$ ant -lib <folder containing spring-boot-antlib-1.3.3.RELEASE.jar>

Тір

The "Using Spring Boot" section includes a more complete example of <u>using Apache Ant with</u> <u>spring-boot-antlib</u>

65.1 Spring Boot Ant tasks

Once the spring-boot-antlib namespace has been declared, the following additional tasks are available.

spring-boot:exejar

The exejar task can be used to creates a Spring Boot executable jar. The following attributes are supported by the task:

Attribute	Description	Required
destfile	The destination jar file to create	Yes
classes	The root directory of Java class files	Yes
start-class	The main application class to run	No (default is first class found declaring a main method)

The following nested elements can be used with the task:

Element	Description
resources	One or more <u>Resource Collections</u> describing a set of <u>Resources</u> that should be added to the content of the created jar file.
lib	One or more <u>Resource Collections</u> that should be added to the set of jar libraries that make up the runtime dependency classpath of the application.

Examples

Specify start-class.

Detect start-class.

```
<exejar destfile="target/my-application.jar" classes="target/classes">
    </lib>
    </lib>
    <//exejar>
```

65.2 spring-boot:findmainclass

The findmainclass task is used internally by exejar to locate a class declaring a main. You can also use this task directly in your build if needed. The following attributes are supported

Attribute	Description	Required
classesroot	The root directory of Java class files	Yes (unless mainclass is specified)
mainclass	Can be used to short-circuit the main class search	No
property	The Ant property that should be set with the result	No (result will be logged if unspecified)

Examples

Find and log.

<findmainclass classesroot="target/classes" />

Find and set.

<findmainclass classesroot="target/classes" property="main-class" />

Override and set.

<findmainclass mainclass="com.foo.MainClass" property="main-class" />

66. Supporting other build systems

If you want to use a build tool other than Maven, Gradle or Ant, you will likely need to develop your own plugin. Executable jars need to follow a specific format and certain entries need to be written in an uncompressed form (see the *executable jar format* section in the appendix for details).

The Spring Boot Maven and Gradle plugins both make use of spring-boot-loader-tools to actually generate jars. You are also free to use this library directly yourself if you need to.

66.1 Repackaging archives

To repackage an existing archive so that it becomes a self-contained executable archive use org.springframework.boot.loader.tools.Repackager. The Repackager class takes a single constructor argument that refers to an existing jar or war archive. Use one of the two available repackage() methods to either replace the original file or write to a new destination. Various settings can also be configured on the repackager before it is run.

66.2 Nested libraries

When repackaging an archive you can include references to dependency files using the org.springframework.boot.loader.tools.Libraries interface. We don't provide any concrete implementations of Libraries here as they are usually build system specific.

If your archive already includes libraries you can use Libraries.NONE.

66.3 Finding a main class

If you don't use Repackager.setMainClass() to specify a main class, the repackager will use <u>ASM</u> to read class files and attempt to find a suitable class with a public static void main(String[] args) method. An exception is thrown if more than one candidate is found.

66.4 Example repackage implementation

Here is a typical example repackage:

67. What to read next

If you're interested in how the build tool plugins work you can look at the <u>spring-boot-tools</u> module on GitHub. More technical details of the <u>executable jar format</u> are covered in the appendix.

If you have specific build-related questions you can check out the "how-to" guides.

Part IX. 'How-to' guides

This section provides answers to some common 'how do I do that...' type of questions that often arise when using Spring Boot. This is by no means an exhaustive list, but it does cover quite a lot.

If you are having a specific problem that we don't cover here, you might want to check out <u>stackoverflow.com</u> to see if someone has already provided an answer; this is also a great place to ask new questions (please use the spring-boot tag).

We're also more than happy to extend this section; If you want to add a 'how-to' you can send us a <u>pull request</u>.

68. Spring Boot application

68.1 Troubleshoot auto-configuration

The Spring Boot auto-configuration tries its best to 'do the right thing', but sometimes things fail and it can be hard to tell why.

There is a really useful ConditionEvaluationReport available in any Spring Boot ApplicationContext. You will see it if you enable DEBUG logging output. If you use the springboot-actuator there is also an autoconfig endpoint that renders the report in JSON. Use that to debug the application and see what features have been added (and which not) by Spring Boot at runtime.

Many more questions can be answered by looking at the source code and the javadoc. Some rules of thumb:

- Look for classes called *AutoConfiguration and read their sources, in particular the @Conditional* annotations to find out what features they enable and when. Add --debug to the command line or a System property -Ddebug to get a log on the console of all the auto-configuration decisions that were made in your app. In a running Actuator app look at the autoconfig endpoint ('/autoconfig' or the JMX equivalent) for the same information.
- Look for classes that are @ConfigurationProperties (e.g. <u>ServerProperties</u>) and read from there the available external configuration options. The @ConfigurationProperties has a name attribute which acts as a prefix to external properties, thus ServerProperties has prefix="server" and its configuration properties are server.port, server.address etc. In a running Actuator app look at the configprops endpoint.
- Look for use of RelaxedPropertyResolver to pull configuration values explicitly out of the Environment. It often is used with a prefix.
- Look for @Value annotations that bind directly to the Environment. This is less flexible than the RelaxedPropertyResolver approach, but does allow some relaxed binding, specifically for OS environment variables (so CAPITALS_AND_UNDERSCORES are synonyms for period.separated).
- Look for @ConditionalOnExpression annotations that switch features on and off in response to SpEL expressions, normally evaluated with placeholders resolved from the Environment.

68.2 Customize the Environment or ApplicationContext before it starts

A SpringApplication has ApplicationListeners and ApplicationContextInitializers that are used to apply customizations to the context or environment. Spring Boot loads a number of such customizations for use internally from META-INF/spring.factories. There is more than one way to register additional ones:

- Programmatically per application by calling the addListeners and addInitializers methods on SpringApplication before you run it.
- Declaratively per application by setting context.initializer.classes or context.listener.classes.
- Declaratively for all applications by adding a META-INF/spring.factories and packaging a jar file that the applications all use as a library.

The SpringApplication sends some special ApplicationEvents to the listeners (even some before the context is created), and then registers the listeners for events published by the ApplicationContext as well. See <u>Section 23.4</u>, "Application events and listeners" in the 'Spring Boot features' section for a complete list.

68.3 Build an ApplicationContext hierarchy (adding a parent or root context)

You can use the ApplicationBuilder class to create parent/child ApplicationContext hierarchies. See <u>Section 23.3, "Fluent builder API</u>" in the 'Spring Boot features' section for more information.

68.4 Create a non-web application

Not all Spring applications have to be web applications (or web services). If you want to execute some code in a main method, but also bootstrap a Spring application to set up the infrastructure to use, then it's easy with the SpringApplication features of Spring Boot. A SpringApplication changes its ApplicationContext class depending on whether it thinks it needs a web application or not. The first thing you can do to help it is to just leave the servlet API dependencies off the classpath. If you can't do that (e.g. you are running 2 applications from the same code base) then you can explicitly call setWebEnvironment(false) on your SpringApplication instance, or set the applicationContextClass property (through the Java API or with external properties). Application code that you want to run as your business logic can be implemented as a CommandLineRunner and dropped into the context as a @Bean definition.

69. Properties & configuration

69.1 Externalize the configuration of SpringApplication

A SpringApplication has been properties (mainly setters) so you can use its Java API as you create the application to modify its behavior. Or you can externalize the configuration using properties in spring.main.*. E.g. in application.properties you might have.

```
spring.main.web_environment=false
spring.main.banner_mode=off
```

and then the Spring Boot banner will not be printed on startup, and the application will not be a web application.

Note

The example above also demonstrates how flexible binding allows the use of underscores (_) as well as dashes (-) in property names.

Properties defined in external configuration overrides the values specified via the Java API with the notable exception of the sources used to create the ApplicationContext. Let's consider this application

```
new SpringApplicationBuilder()
   .bannerMode(Banner.Mode.OFF)
   .sources(demo.MyApp.class)
   .run(args);
```

used with the following configuration:

```
spring.main.sources=com.acme.Config,com.acme.ExtraConfig
spring.main.banner_mode=console
```

The actual application will *now* show the banner (as overridden by configuration) and use three sources for the ApplicationContext (in that order): demo.MyApp, com.acme.Config, com.acme.ExtraConfig.

69.2 Change the location of external properties of an application

By default properties from different sources are added to the Spring Environment in a defined order (see <u>Chapter 24, Externalized Configuration</u> in the 'Spring Boot features' section for the exact order).

A nice way to augment and modify this is to add <code>@PropertySource</code> annotations to your application sources. Classes passed to the <code>SpringApplication</code> static convenience methods, and those added using <code>setSources()</code> are inspected to see if they have <code>@PropertySources</code>, and if they do, those properties are added to the <code>Environment</code> early enough to be used in all phases of the <code>ApplicationContext</code> lifecycle. Properties added in this way have lower priority than any added using the default locations (e.g. application.properties), system properties, environment variables or the command line.

You can also provide System properties (or environment variables) to change the behavior:

- spring.config.name (SPRING_CONFIG_NAME), defaults to application as the root of the file name.
- spring.config.location (SPRING_CONFIG_LOCATION) is the file to load (e.g. a classpath resource or a URL). A separate Environment property source is set up for this document and it can be overridden by system properties, environment variables or the command line.

No matter what you set in the environment, Spring Boot will always load application.properties as described above. If YAML is used then files with the '.yml' extension are also added to the list by default.

Spring Boot logs the configuration files that are loaded at DEBUG level and the candidates it has not found at TRACE level.

See <u>ConfigFileApplicationListener</u> for more detail.

69.3 Use 'short' command line arguments

Some people like to use (for example) --port=9000 instead of --server.port=9000 to set configuration properties on the command line. You can easily enable this by using placeholders in application.properties, e.g.

server.port=\${port:8080}

Тір

If you are inheriting from the spring-boot-starter-parent POM, the default filter token of the maven-resources-plugins has been changed from \${*} to @ (i.e. @maven.token@ instead of \${maven.token}) to prevent conflicts with Spring-style placeholders. If you have enabled maven filtering for the application.properties directly, you may want to also change the default filter token to use <u>other delimiters</u>.

Note

In this specific case the port binding will work in a PaaS environment like Heroku and Cloud Foundry, since in those two platforms the PORT environment variable is set automatically and Spring can bind to capitalized synonyms for Environment properties.

69.4 Use YAML for external properties

YAML is a superset of JSON and as such is a very convenient syntax for storing external properties in a hierarchical format. E.g.

```
spring:
    application:
        name: cruncher
    datasource:
        driverClassName: com.mysql.jdbc.Driver
        url: jdbc:mysql://localhost/test
server:
    port: 9000
```

Create a file called application.yml and stick it in the root of your classpath, and also add snakeyaml to your dependencies (Maven coordinates org.yaml:snakeyaml, already included if

you use the spring-boot-starter). A YAML file is parsed to a Java Map<String, Object> (like a JSON object), and Spring Boot flattens the map so that it is 1-level deep and has period-separated keys, a lot like people are used to with Properties files in Java.

The example YAML above corresponds to an application.properties file

```
spring.application.name=cruncher
spring.datasource.driverClassName=com.mysql.jdbc.Driver
spring.datasource.url=jdbc:mysql://localhost/test
server.port=9000
```

See <u>Section 24.6, "Using YAML instead of Properties</u>" in the 'Spring Boot features' section for more information about YAML.

69.5 Set the active Spring profiles

The Spring Environment has an API for this, but normally you would set a System property (spring.profiles.active) or an OS environment variable (SPRING_PROFILES_ACTIVE). E.g. launch your application with a -D argument (remember to put it before the main class or jar archive):

\$ java -jar -Dspring.profiles.active=production demo-0.0.1-SNAPSHOT.jar

In Spring Boot you can also set the active profile in application.properties, e.g.

spring.profiles.active=production

A value set this way is replaced by the System property or environment variable setting, but not by the SpringApplicationBuilder.profiles() method. Thus the latter Java API can be used to augment the profiles without changing the defaults.

See <u>Chapter 25, Profiles</u> in the 'Spring Boot features' section for more information.

69.6 Change configuration depending on the environment

A YAML file is actually a sequence of documents separated by --- lines, and each document is parsed separately to a flattened map.

If a YAML document contains a spring.profiles key, then the profiles value (comma-separated list of profiles) is fed into the Spring Environment.acceptsProfiles() and if any of those profiles is active that document is included in the final merge (otherwise not).

Example:

```
server:
    port: 9000
----
spring:
    profiles: development
server:
    port: 9001
----
spring:
    profiles: production
server:
    port: 0
```

In this example the default port is 9000, but if the Spring profile 'development' is active then the port is 9001, and if 'production' is active then it is 0.

The YAML documents are merged in the order they are encountered (so later values override earlier ones).

To do the same thing with properties files you can use application-\${profile}.properties to specify profile-specific values.

69.7 Discover built-in options for external properties

Spring Boot binds external properties from application.properties (or .yml) (and other places) into an application at runtime. There is not (and technically cannot be) an exhaustive list of all supported properties in a single location because contributions can come from additional jar files on your classpath.

A running application with the Actuator features has a configprops endpoint that shows all the bound and bindable properties available through @ConfigurationProperties.

The appendix includes an <u>application.properties</u> example with a list of the most common properties supported by Spring Boot. The definitive list comes from searching the source code for @ConfigurationProperties and @Value annotations, as well as the occasional use of RelaxedPropertyResolver.

70. Embedded servlet containers

70.1 Add a Servlet, Filter or Listener to an application

There are two ways to add Servlet, Filter, ServletContextListener and the other listeners supported by the Servlet spec to your application. You can either provide Spring beans for them, or enable scanning for Servlet components.

Add a Servlet, Filter or Listener using a Spring bean

To add a Servlet, Filter, or Servlet *Listener provide a @Bean definition for it. This can be very useful when you want to inject configuration or dependencies. However, you must be very careful that they don't cause eager initialization of too many other beans because they have to be installed in the container very early in the application lifecycle (e.g. it's not a good idea to have them depend on your DataSource or JPA configuration). You can work around restrictions like that by initializing them lazily when first used instead of on initialization.

In the case of Filters and Servlets you can also add mappings and init parameters by adding a FilterRegistrationBean or ServletRegistrationBean instead of or as well as the underlying component.

Note

If no dispatcherType is specified on a filter registration, it will match FORWARD, INCLUDE and REQUEST. If async has been enabled, it will match ASYNC as well.

If you are migrating a filter that has no dispatcher element in web.xml you will need to specify a dispatcherType yourself:

```
@Bean
public FilterRegistrationBean myFilterRegistration() {
    FilterRegistrationBean registration = new FilterRegistrationBean();
    registration.setDispatcherTypes(DispatcherType.REQUEST);
    ....
    return registration;
}
```

Disable registration of a Servlet or Filter

As <u>described above</u> any <u>Servlet</u> or <u>Filter</u> beans will be registered with the servlet container automatically. To disable registration of a particular <u>Filter</u> or <u>Servlet</u> bean create a registration bean for it and mark it as disabled. For example:

```
@Bean
public FilterRegistrationBean registration(MyFilter filter) {
    FilterRegistrationBean registration = new FilterRegistrationBean(filter);
    registration.setEnabled(false);
    return registration;
}
```

Add Servlets, Filters, and Listeners using classpath scanning

@WebServlet, @WebFilter, and @WebListener annotated classes can be automatically registered with an embedded servlet container by annotating a @Configuration class with @ServletComponentScan and specifying the package(s) containing the components that you want to register. By default, @ServletComponentScan will scan from the package of the annotated class.

70.2 Change the HTTP port

In a standalone application the main HTTP port defaults to 8080, but can be set with server.port (e.g. in application.properties or as a System property). Thanks to relaxed binding of Environment values you can also use SERVER_PORT (e.g. as an OS environment variable).

To switch off the HTTP endpoints completely, but still create a WebApplicationContext, use server.port=-1 (this is sometimes useful for testing).

For more details look at <u>the section called "Customizing embedded servlet containers"</u> in the 'Spring Boot features' section, or the <u>ServerProperties</u> source code.

70.3 Use a random unassigned HTTP port

To scan for a free port (using OS natives to prevent clashes) use server.port=0.

70.4 Discover the HTTP port at runtime

You can access the port the server is running on from log output or from the EmbeddedWebApplicationContext via its EmbeddedServletContainer. The best way to get that and be sure that it has initialized is to add a @Bean of type ApplicationListener<EmbeddedServletContainerInitializedEvent> and pull the container out of the event when it is published.

A useful practice for use with @WebIntegrationTest is to set server.port=0 and then inject the actual ('local') port as a @Value. For example:

```
@RunWith(SpringJUnit4ClassRunner.class)
@SpringApplicationConfiguration(SampleDataJpaApplication.class)
@WebIntegrationTest("server.port:0")
public class CityRepositoryIntegrationTests {
    @Autowired
    EmbeddedWebApplicationContext server;
    @Value("${local.server.port}")
    int port;
    // ...
}
```

Note

Don't try to inject the port with <code>@Value</code> in a regular application. As we just saw, the value is only set once the container has initialized; contrary to a test, application code callbacks are processed early (i.e. before the value is actually available).

70.5 Configure SSL

SSL can be configured declaratively by setting the various server.ssl.* properties, typically in application.properties or application.yml. For example:

```
server.port=8443
server.ssl.key-store=classpath:keystore.jks
server.ssl.key-store-password=secret
server.ssl.key-password=another-secret
```

See <u>Ssl</u> for details of all of the supported properties.

Using configuration like the example above means the application will no longer support plain HTTP connector at port 8080. Spring Boot doesn't support the configuration of both an HTTP connector and an HTTPS connector via application.properties. If you want to have both then you'll need to configure one of them programmatically. It's recommended to use application.properties to configure HTTPS as the HTTP connector is the easier of the two to configure programmatically. See the spring-boot-sample-tomcat-multi-connectors sample project for an example.

70.6 Configure Access Logging

Access logs can be configured for Tomcat and Undertow via their respective namespaces.

For instance, the following logs access on Tomcat with a custom pattern.

```
server.tomcat.basedir=my-tomcat
server.tomcat.accesslog.enabled=true
server.tomcat.accesslog.pattern=%t %a "%r" %s (%D ms)
```

Note

The default location for logs is a logs directory relative to the tomcat base dir and said directory is a temp directory by default so you may want to fix Tomcat's base directory or use an absolute path for the logs. In the example above, the logs will be available in m_y -tomcat/logs relative to the working directory of the application.

Access logging for undertow can be configured in a similar fashion

```
server.undertow.accesslog.enabled=true
server.undertow.accesslog.pattern=%t %a "%r" %s (%D ms)
```

Logs are stored in a logs directory relative to the working directory of the application. This can be customized via server.undertow.accesslog.directory.

70.7 Use behind a front-end proxy server

Your application might need to send 302 redirects or render content with absolute links back to itself. When running behind a proxy, the caller wants a link to the proxy, and not to the physical address of the machine hosting your app. Typically such situations are handled via a contract with the proxy, which will add headers to tell the back end how to construct links to itself.

If the proxy adds conventional X-Forwarded-For and X-Forwarded-Proto headers (most do this out of the box) the absolute links should be rendered correctly as long as server.use-forward-headers is set to true in your application.properties.

Note

If your application is running in Cloud Foundry or Heroku the server.use-forward-headers property will default to true if not specified. In all other instances it defaults to false.

Customize Tomcat's proxy configuration

If you are using Tomcat you can additionally configure the names of the headers used to carry "forwarded" information:

```
server.tomcat.remote-ip-header=x-your-remote-ip-header
server.tomcat.protocol-header=x-your-protocol-header
```

Tomcat is also configured with a default regular expression that matches internal proxies that are to be trusted. By default, IP addresses in 10/8, 192.168/16, 169.254/16 and 127/8 are trusted. You can customize the valve's configuration by adding an entry to application.properties, e.g.

```
\texttt{server.tomcat.internal-proxies=192\backslash.168\backslash.\backslash\backslashd{1,3}\backslash\backslash.\backslash\backslashd{1,3}}
```

Note

The double backslashes are only required when you're using a properties file for configuration. If you are using YAML, single backslashes are sufficient and a value that's equivalent to the one shown above would be $192 \\ . \\ d{1,3} \\ . \\ d{1,3}$.

Note

You can trust all proxies by setting the internal-proxies to empty (but don't do this in production).

You can take complete control of the configuration of Tomcat's RemotelpValve by switching the automatic one off (i.e. set server.use-forward-headers=false) and adding a new valve instance in a TomcatEmbeddedServletContainerFactory bean.

70.8 Configure Tomcat

Generally you can follow the advice from <u>Section 69.7</u>, "Discover built-in options for external properties" about @ConfigurationProperties (ServerProperties is the main one here), but also look at EmbeddedServletContainerCustomizer and various Tomcat-specific *Customizers that you can add in one of those. The Tomcat APIs are quite rich so once you have access to the TomcatEmbeddedServletContainerFactory you can modify it in a number of ways. Or the nuclear option is to add your own TomcatEmbeddedServletContainerFactory.

70.9 Enable Multiple Connectors with Tomcat

Addaorg.apache.catalina.connector.ConnectortotheTomcatEmbeddedServletContainerFactorywhich can allow multiple connectors, e.g. HTTP andHTTPS connector:

```
@Bean
public EmbeddedServletContainerFactory servletContainer() {
   TomcatEmbeddedServletContainerFactory tomcat = new TomcatEmbeddedServletContainerFactory();
   tomcat.addAdditionalTomcatConnectors(createSslConnector());
   return tomcat;
}
private Connector createSslConnector() {
   Connector connector = new Connector("org.apache.coyote.httpl1.Httpl1NioProtocol");
   Httpl1NioProtocol protocol = (Httpl1NioProtocol) connector.getProtocolHandler();
   try {
```

70.10 Use Jetty instead of Tomcat

The Spring Boot starters (spring-boot-starter-web in particular) use Tomcat as an embedded container by default. You need to exclude those dependencies and include the Jetty one instead. Spring Boot provides Tomcat and Jetty dependencies bundled together as separate starters to help make this process as easy as possible.

Example in Maven:

```
<dependency>
<groupId>org.springframework.boot</groupId>
<artifactId>spring-boot-starter-web</artifactId>
<exclusions>
<exclusion>
<groupId>org.springframework.boot</groupId>
<artifactId>spring-boot-starter-tomcat</artifactId>
</exclusion>
</exclusions>
</dependency>
<groupId>org.springframework.boot</groupId>
<artifactId>spring-boot-starter-jetty</artifactId>
</dependency>
</dependency>
```

Example in Gradle:

```
configurations {
   compile.exclude module: "spring-boot-starter-tomcat"
}
dependencies {
   compile("org.springframework.boot:spring-boot-starter-web:1.3.3.RELEASE")
   compile("org.springframework.boot:spring-boot-starter-jetty:1.3.3.RELEASE")
   // ...
}
```

70.11 Configure Jetty

Generally you can follow the advice from <u>Section 69.7</u>, "Discover built-in options for external properties" about @ConfigurationProperties (ServerProperties is the main one here), but also look at EmbeddedServletContainerCustomizer. The Jetty APIs are quite rich so once you have access to the JettyEmbeddedServletContainerFactory you can modify it in a number of ways. Or the nuclear option is to add your own JettyEmbeddedServletContainerFactory.

70.12 Use Undertow instead of Tomcat

Using Undertow instead of Tomcat is very similar to <u>using Jetty instead of Tomcat</u>. You need to exclude the Tomcat dependencies and include the Undertow starter instead.

Example in Maven:

```
<dependency>
<groupId>org.springframework.boot</groupId>
<artifactId>spring-boot-starter-web</artifactId>
<exclusions>
<groupId>org.springframework.boot</groupId>
<artifactId>spring-boot-starter-tomcat</artifactId>
</exclusion>
</exclusions>
</dependency>
<dependency>
<groupId>org.springframework.boot</groupId>
<artifactId>spring-boot-starter-undertow</artifactId>
</dependency>
```

Example in Gradle:

```
configurations {
   compile.exclude module: "spring-boot-starter-tomcat"
}
dependencies {
   compile("org.springframework.boot:spring-boot-starter-web:1.3.3.RELEASE")
   compile("org.springframework.boot:spring-boot-starter-undertow:1.3.3.RELEASE")
   // ...
}
```

70.13 Configure Undertow

Generally you can follow the advice from <u>Section 69.7</u>, "Discover built-in options for external properties" about @ConfigurationProperties (ServerProperties and ServerProperties.Undertow are the main ones here), but also look at EmbeddedServletContainerCustomizer. Once you have access to the UndertowEmbeddedServletContainerFactory you can use an UndertowBuilderCustomizer to modify Undertow's configuration to meet your needs. Or the nuclear option is to add your own UndertowEmbeddedServletContainerFactory.

70.14 Enable Multiple Listeners with Undertow

Add an UndertowBuilderCustomizer to the UndertowEmbeddedServletContainerFactory and add a listener to the Builder:

```
@Bean
public UndertowEmbeddedServletContainerFactory embeddedServletContainerFactory() {
    UndertowEmbeddedServletContainerFactory factory = new UndertowEmbeddedServletContainerFactory();
    factory.addBuilderCustomizers(new UndertowBuilderCustomizer() {
        @Override
        public void customize(Builder builder) {
            builder.addHttpListener(8080, "0.0.0.0");
        }
    });
    return factory;
}
```

70.15 Use Tomcat 7

Tomcat 7 works with Spring Boot, but the default is to use Tomcat 8. If you cannot use Tomcat 8 (for example, because you are using Java 1.6) you will need to change your classpath to reference Tomcat 7.

Use Tomcat 7 with Maven

If you are using the starter poms and parent you can just change the Tomcat version property, e.g. for a simple webapp or service:

```
<properties>
  <tomcat.version>7.0.59</tomcat.version>
</properties>
  <dependencies>
    ...
    <dependency>
        <groupId>org.springframework.boot</groupId>
        <artifactId>spring-boot-starter-web</artifactId>
        </dependency>
    ...
  </dependencies>
```

Use Tomcat 7 with Gradle

You can change the Tomcat version by setting the tomcat.version property:

```
ext['tomcat.version'] = '7.0.59'
dependencies {
    compile 'org.springframework.boot:spring-boot-starter-web'
}
```

70.16 Use Jetty 8

Jetty 8 works with Spring Boot, but the default is to use Jetty 9. If you cannot use Jetty 9 (for example, because you are using Java 1.6) you will need to change your classpath to reference Jetty 8. You will also need to exclude Jetty's WebSocket-related dependencies.

Use Jetty 8 with Maven

If you are using the starter poms and parent you can just add the Jetty starter with the required WebSocket exclusion and change the version properties, e.g. for a simple webapp or service:

```
<properties>
   <jetty.version>8.1.15.v20140411</jetty.version>
   <jetty-jsp.version>2.2.0.v201112011158</jetty-jsp.version>
</properties>
<dependencies>
    <dependency>
       <groupId>org.springframework.boot</groupId>
       <artifactId>spring-boot-starter-web</artifactId>
       <exclusions>
            <exclusion>
               <groupId>org.springframework.boot</groupId>
                <artifactId>spring-boot-starter-tomcat</artifactId>
           </exclusion>
       </exclusions>
   </dependency>
    <dependency:
       <groupId>org.springframework.boot</groupId>
       <artifactId>spring-boot-starter-jetty</artifactId>
```

Use Jetty 8 with Gradle

You can set the jetty.version property and exclude the WebSocket dependency, e.g. for a simple webapp or service:

```
ext['jetty.version'] = '8.1.15.v20140411'
dependencies {
    compile ('org.springframework.boot:spring-boot-starter-web') {
        exclude group: 'org.springframework.boot', module: 'spring-boot-starter-tomcat'
    }
    compile ('org.springframework.boot:spring-boot-starter-jetty') {
        exclude group: 'org.eclipse.jetty.websocket'
    }
}
```

70.17 Create WebSocket endpoints using @ServerEndpoint

If you want to use @ServerEndpoint in a Spring Boot application that used an embedded container, you must declare a single ServerEndpointExporter @Bean:

```
@Bean
public ServerEndpointExporter serverEndpointExporter() {
    return new ServerEndpointExporter();
}
```

This bean will register any @ServerEndpoint annotated beans with the underlying WebSocket container. When deployed to a standalone servlet container this role is performed by a servlet container initializer and the ServerEndpointExporter bean is not required.

70.18 Enable HTTP response compression

HTTP response compression is supported by Jetty, Tomcat, and Undertow. It can be enabled via application.properties:

server.compression.enabled=true

By default, responses must be at least 2048 bytes in length for compression to be performed. This can be configured using the server.compression.min-response-size property.

By default, responses will only be compressed if their content type is one of the following:

- text/html
- text/xml
- text/plain
- text/css

This can be configured using the server.compression.mime-types property.

71. Spring MVC

71.1 Write a JSON REST service

Any Spring @RestController in a Spring Boot application should render JSON response by default as long as Jackson2 is on the classpath. For example:

```
@RestController
public class MyController {
    @RequestMapping("/thing")
    public MyThing thing() {
        return new MyThing();
    }
}
```

As long as MyThing can be serialized by Jackson2 (e.g. a normal POJO or Groovy object) then <u>localhost:8080/thing</u> will serve a JSON representation of it by default. Sometimes in a browser you might see XML responses because browsers tend to send accept headers that prefer XML.

71.2 Write an XML REST service

If you have the Jackson XML extension (jackson-dataformat-xml) on the classpath, it will be used to render XML responses and the very same example as we used for JSON would work. To use it, add the following dependency to your project:

```
<dependency>
    <groupId>com.fasterxml.jackson.dataformat</groupId>
    <artifactId>jackson-dataformat-xml</artifactId>
</dependency>
```

You may also want to add a dependency on Woodstox. It's faster than the default StAX implementation provided by the JDK and also adds pretty print support and improved namespace handling:

```
<dependency>
    <groupId>org.codehaus.woodstox</groupId>
    <artifactId>woodstox-core-asl</artifactId>
</dependency>
```

If Jackson's XML extension is not available, JAXB (provided by default in the JDK) will be used, with the additional requirement to have MyThing annotated as @XmlRootElement:

```
@XmlRootElement
public class MyThing {
    private String name;
    // .. getters and setters
}
```

To get the server to render XML instead of JSON you might have to send an Accept: text/xml header (or use a browser).

71.3 Customize the Jackson ObjectMapper

Spring MVC (client and server side) uses HttpMessageConverters to negotiate content conversion in an HTTP exchange. If Jackson is on the classpath you already get the default converter(s) provided by Jackson2ObjectMapperBuilder. The ObjectMapper (or XmlMapper for Jackson XML converter) instance created by default have the following customized properties:

- MapperFeature.DEFAULT_VIEW_INCLUSION is disabled
- DeserializationFeature.FAIL_ON_UNKNOWN_PROPERTIES is disabled

Spring Boot has also some features to make it easier to customize this behavior.

You can configure the ObjectMapper and XmlMapper instances using the environment. Jackson provides an extensive suite of simple on/off features that can be used to configure various aspects of its processing. These features are described in six enums in Jackson which map onto properties in the environment:

Jackson enum	Environment property	
com.fasterxml.jackson.databind.Deseri	iæð pizing iojaReketonrædeserialization. <featu false</featu 	re_name>=tru
com.fasterxml.jackson.core.JsonGenera	at spr.Hegatjærek son.generator. <feature_nam false</feature_nam 	e>=true
com.fasterxml.jackson.databind.Mapper	rF spating .jackson.mapper. <feature_name>= false</feature_name>	true
com.fasterxml.jackson.core.JsonParser	r. Spaing rejackson.parser. <feature_name>= false</feature_name>	true
com.fasterxml.jackson.databind.Serial	li spatingnFjaatkusten. serialization. <feature false</feature 	_name>=true
com.fasterxml.jackson.annotation.Jsor	nT sprlingejandkamke. serialization- inclusion=always non_null non_absent non_default non_empty	
For example to en	able pretty print set	

For example, to enable pretty print, set spring.jackson.serialization.indent_output=true. Note that, thanks to the use of relaxed binding, the case of indent_output doesn't have to match the case of the corresponding enum constant which is INDENT_OUTPUT.

If you want to replace the default ObjectMapper completely, define a @Bean of that type and mark it as @Primary.

Defining a @Bean of type Jackson2ObjectMapperBuilder will allow you to customize both default ObjectMapper and XmlMapper (used in MappingJackson2HttpMessageConverter and MappingJackson2XmlHttpMessageConverter respectively).

Another way to customize Jackson is to add beans of type com.fasterxml.jackson.databind.Module to your context. They will be registered with every bean of type ObjectMapper, providing a global mechanism for contributing custom modules when you add new features to your application.

Finally, if you provide any @Beans of type MappingJackson2HttpMessageConverter then they will replace the default value in the MVC configuration. Also, a convenience bean is provided of type HttpMessageConverters (always available if you use the default MVC configuration) which has some useful methods to access the default and user-enhanced message converters.

See also the <u>Section 71.4</u>, "Customize the @ResponseBody rendering" section and the <u>WebMvcAutoConfiguration</u> source code for more details.

71.4 Customize the @ResponseBody rendering

Spring uses HttpMessageConverters to render @ResponseBody (or responses from @RestController). You can contribute additional converters by simply adding beans of that type in a Spring Boot context. If a bean you add is of a type that would have been included by default anyway (like MappingJackson2HttpMessageConverter for JSON conversions) then it will replace the default value. A convenience bean is provided of type HttpMessageConverters (always available if you use the default MVC configuration) which has some useful methods to access the default and user-enhanced message converters (useful, for example if you want to manually inject them into a custom RestTemplate).

As in normal MVC usage, any WebMvcConfigurerAdapter beans that you provide can also contribute converters by overriding the configureMessageConverters method, but unlike with normal MVC, you can supply only additional converters that you need (because Spring Boot uses the same mechanism to contribute its defaults). Finally, if you opt-out of the Spring Boot default MVC configuration by providing your own @EnableWebMvc configuration, then you can take control completely and do everything manually using getMessageConverters from WebMvcConfigurationSupport.

See the <u>WebMvcAutoConfiguration</u> source code for more details.

71.5 Handling Multipart File Uploads

Spring Boot embraces the Servlet 3 javax.servlet.http.Part API to support uploading files. By default Spring Boot configures Spring MVC with a maximum file of 1Mb per file and a maximum of 10Mb of file data in a single request. You may override these values, as well as the location to which intermediate data is stored (e.g., to the /tmp directory) and the threshold past which data is flushed to disk by using the properties exposed in the MultipartProperties class. If you want to specify that files be unlimited, for example, set the multipart.maxFileSize property to -1.

The multipart support is helpful when you want to receive multipart encoded file data as a @RequestParam-annotated parameter of type MultipartFile in a Spring MVC controller handler method.

See the $\underline{\texttt{MultipartAutoConfiguration}}$ source for more details.

71.6 Switch off the Spring MVC DispatcherServlet

Spring Boot wants to serve all content from the root of your application / down. If you would rather map your own servlet to that URL you can do it, but of course you may lose some of the other Boot MVC features. To add your own servlet and map it to the root resource just declare a <code>@Bean</code> of type <code>Servlet</code> and give it the special bean name <code>dispatcherServlet</code> (You can also create a bean of a different type with that name if you want to switch it off and not replace it).

71.7 Switch off the Default MVC configuration

The easiest way to take complete control over MVC configuration is to provide your own @Configuration with the @EnableWebMvc annotation. This will leave all MVC configuration in your hands.

71.8 Customize ViewResolvers

A ViewResolver is a core component of Spring MVC, translating view names in @Controller to actual View implementations. Note that ViewResolvers are mainly used in UI applications, rather than REST-style services (a View is not used to render a @ResponseBody). There are many implementations of ViewResolver to choose from, and Spring on its own is not opinionated about which ones you should use. Spring Boot, on the other hand, installs one or two for you depending on what it finds on the classpath and in the application context. The DispatcherServlet uses all the resolvers it finds in the application context, trying each one in turn until it gets a result, so if you are adding your own you have to be aware of the order and in which position your resolver is added.

WebMvcAutoConfiguration adds the following ViewResolvers to your context:

- An InternalResourceViewResolver with bean id 'defaultViewResolver'. This one locates physical resources that can be rendered using the DefaultServlet (e.g. static resources and JSP pages if you are using those). It applies a prefix and a suffix to the view name and then looks for a physical resource with that path in the servlet context (defaults are both empty, but accessible for external configuration via spring.mvc.view.prefix and spring.mvc.view.suffix). It can be overridden by providing a bean of the same type.
- A BeanNameViewResolver with id 'beanNameViewResolver'. This is a useful member of the view resolver chain and will pick up any beans with the same name as the View being resolved. It shouldn't be necessary to override or replace it.
- A ContentNegotiatingViewResolver with id 'viewResolver' is only added if there **are** actually beans of type View present. This is a 'master' resolver, delegating to all the others and attempting to find a match to the 'Accept' HTTP header sent by the client. There is a useful <u>blog about ContentNegotiatingViewResolver</u> that you might like to study to learn more, and also look at the source code for detail. You can switch off the auto-configured ContentNegotiatingViewResolver by defining a bean named 'viewResolver'.
- If you use Thymeleaf you will also have a ThymeleafViewResolver with id 'thymeleafViewResolver'. It looks for resources by surrounding the view name with a prefix and suffix (externalized to spring.thymeleaf.prefix and spring.thymeleaf.suffix, defaults 'classpath:/templates/' and '.html' respectively). It can be overridden by providing a bean of the same name.
- If you use FreeMarker you will also have a FreeMarkerViewResolver with id 'freeMarkerViewResolver'. It looks for resources in a loader path (externalized to spring.freemarker.templateLoaderPath, default 'classpath:/templates/') by surrounding the view name with a prefix and suffix (externalized to spring.freemarker.prefix and spring.freemarker.suffix, with empty and '.ftl' defaults respectively). It can be overridden by providing a bean of the same name.
- If you use Groovy templates (actually if groovy-templates is on your classpath) you will also have a GroovyMarkupViewResolver with id 'groovyMarkupViewResolver'. It looks for resources in a loader path by surrounding the view name with a prefix and suffix (externalized to spring.groovy.template.prefix and spring.groovy.template.suffix, defaults 'classpath:/templates/' and '.tpl' respectively). It can be overridden by providing a bean of the same name.
- If you use Velocity you will also have a VelocityViewResolver with id 'velocityViewResolver'. It looks for resources in a loader path (externalized to spring.velocity.resourceLoaderPath,

default 'classpath:/templates/') by surrounding the view name with a prefix and suffix (externalized to spring.velocity.prefix and spring.velocity.suffix, with empty and '.vm' defaults respectively). It can be overridden by providing a bean of the same name.

CheckoutWebMvcAutoConfiguration,ThymeleafAutoConfiguration,FreeMarkerAutoConfiguration,GroovyTemplateAutoConfigurationandVelocityAutoConfiguration

71.9 Velocity

By default, Spring Boot configures a VelocityViewResolver. If you need a VelocityLayoutViewResolver instead, you can easily configure your own by creating a bean with name velocityViewResolver. You can also inject the VelocityProperties instance to apply the base defaults to your custom view resolver.

The following example replaces the auto-configured velocity view resolver with a VelocityLayoutViewResolver defining a customized layoutUrl and all settings that would have been applied from the auto-configuration:

```
@Bean(name = "velocityViewResolver")
public VelocityLayoutViewResolver velocityViewResolver(VelocityProperties properties) {
    VelocityLayoutViewResolver resolver = new VelocityLayoutViewResolver();
    properties.applyToViewResolver(resolver);
    resolver.setLayoutUrl("layout/default.vm");
    return resolver;
}
```

72. Logging

Spring Boot has no mandatory logging dependency, except for the commons-logging API, of which there are many implementations to choose from. To use <u>Logback</u> you need to include it, and some bindings for commons-logging on the classpath. The simplest way to do that is through the starter poms which all depend on spring-boot-starter-logging. For a web application you only need spring-boot-starter-web since it depends transitively on the logging starter. For example, using Maven:

```
<dependency>
    <groupId>org.springframework.boot</groupId>
        <artifactId>spring-boot-starter-web</artifactId>
</dependency>
```

Spring Boot has a LoggingSystem abstraction that attempts to configure logging based on the content of the classpath. If Logback is available it is the first choice.

If the only change you need to make to logging is to set the levels of various loggers then you can do that in application.properties using the "logging.level" prefix, e.g.

```
logging.level.org.springframework.web=DEBUG
logging.level.org.hibernate=ERROR
```

You can also set the location of a file to log to (in addition to the console) using "logging.file".

To configure the more fine-grained settings of a logging system you need to use the native configuration format supported by the LoggingSystem in question. By default Spring Boot picks up the native configuration from its default location for the system (e.g. classpath:logback.xml for Logback), but you can set the location of the config file using the "logging.config" property.

72.1 Configure Logback for logging

If you put a logback.xml in the root of your classpath it will be picked up from there (or logbackspring.xml to take advantage of the templating features provided by Boot). Spring Boot provides a default base configuration that you can include if you just want to set levels, e.g.

If you look at that base.xml in the spring-boot jar, you will see that it uses some useful System properties which the LoggingSystem takes care of creating for you. These are:

- \${PID} the current process ID.
- \${LOG_FILE} if logging.file was set in Boot's external configuration.
- \${LOG_PATH} if logging.path was set (representing a directory for log files to live in).
- \${LOG_EXCEPTION_CONVERSION_WORD} if logging.exception-conversion-word was set in Boot's external configuration.

Spring Boot also provides some nice ANSI colour terminal output on a console (but not in a log file) using a custom Logback converter. See the default base.xml configuration for details.

If Groovy is on the classpath you should be able to configure Logback with logback.groovy as well (it will be given preference if present).

Configure logback for file only output

If you want to disable console logging and write output only to a file you need a custom logbackspring.xml that imports file-appender.xml but not console-appender.xml:

You also need to add logging.file to your application.properties:

logging.file=myapplication.log

72.2 Configure Log4j for logging

Spring Boot also supports either Log4j or Log4j 2 for logging configuration, but only if one of them is on the classpath. If you are using the starter poms for assembling dependencies that means you have to exclude Logback and then include your chosen version of Log4j instead. If you aren't using the starter poms then you need to provide commons-logging (at least) in addition to your chosen version of Log4j.

The simplest path is probably through the starter poms, even though it requires some jiggling with excludes, .e.g. in Maven:

```
<dependency>
   <groupId>org.springframework.boot</groupId>
   <artifactId>spring-boot-starter-web</artifactId>
</dependency>
<dependency>
   <groupId>org.springframework.boot</groupId>
   <artifactId>spring-boot-starter</artifactId>
   <exclusions>
        <exclusion>
           <groupId>org.springframework.boot</groupId>
            <artifactId>spring-boot-starter-logging</artifactId>
       </exclusion>
   </exclusions>
</dependency>
<dependency>
   <groupId>org.springframework.boot</groupId>
    <artifactId>spring-boot-starter-log4j</artifactId>
</dependency>
```

To use Log4j 2, simply depend on spring-boot-starter-log4j2 rather than spring-bootstarter-log4j.

Note

The use of one of the Log4j starters gathers together the dependencies for common logging requirements (e.g. including having Tomcat use java.util.logging but configuring the output using Log4j or Log4j 2). See the Actuator Log4j or Log4j 2 samples for more detail and to see it in action.

Use YAML or JSON to configure Log4j 2

In addition to its default XML configuration format, Log4j 2 also supports YAML and JSON configuration files. To configure Log4j 2 to use an alternative configuration file format, add the appropriate dependencies to the classpath and name your configuration files to match your chosen file format:

Format	Dependencies	File names
YAML	com.fasterxml.jackson.core:jackson-databind com.fasterxml.jackson.dataformat:jackson-dataformat- yaml	log4j2.yaml log4j2.yml
JSON	com.fasterxml.jackson.core:jackson-databind	log4j2.jsor log4j2.jsn

73. Data Access

73.1 Configure a DataSource

To override the default settings just define a <code>@Bean</code> of your own of type <code>DataSource</code>. Spring Boot provides a utility builder class <code>DataSourceBuilder</code> that can be used to create one of the standard ones (if it is on the classpath), or you can just create your own, and bind it to a set of <code>Environment</code> properties as explained in the section called "Third-party configuration", e.g.

```
@Bean
@ConfigurationProperties(prefix="datasource.mine")
public DataSource dataSource() {
    return new FancyDataSource();
}
datasource.mine.jdbcUrl=jdbc:h2:mem:mydb
datasource.mine.user=sa
datasource.mine.poolSize=30
```

See <u>Section 29.1, "Configure a DataSource</u>" in the 'Spring Boot features' section and the <u>DataSourceAutoConfiguration</u> class for more details.

73.2 Configure Two DataSources

Creating more than one data source works the same as creating the first one. You might want to mark one of them as @Primary if you are using the default auto-configuration for JDBC or JPA (then that one will be picked up by any @Autowired injections).

```
@Bean
@Primary
@ConfigurationProperties(prefix="datasource.primary")
public DataSource primaryDataSource() {
    return DataSourceBuilder.create().build();
}
@Bean
@ConfigurationProperties(prefix="datasource.secondary")
public DataSource secondaryDataSource() {
    return DataSourceBuilder.create().build();
}
```

73.3 Use Spring Data repositories

Spring Data can create implementations for you of @Repository interfaces of various flavors. Spring Boot will handle all of that for you as long as those @Repositories are included in the same package (or a sub-package) of your @EnableAutoConfiguration class.

For many applications all you will need is to put the right Spring Data dependencies on your classpath (there is a spring-boot-starter-data-jpa for JPA and a spring-boot-starter-datamongodb for Mongodb), create some repository interfaces to handle your @Entity objects. Examples are in the <u>JPA sample</u> or the <u>Mongodb sample</u>.

Spring Boot tries to guess the location of your @Repository definitions, based on the @EnableAutoConfiguration it finds. To get more control, use the @EnableJpaRepositories annotation (from Spring Data JPA).

73.4 Separate @Entity definitions from Spring configuration

Spring Boot tries to guess the location of your @Entity definitions, based on the @EnableAutoConfiguration it finds. To get more control, you can use the @EntityScan annotation, e.g.

```
@Configuration
@EnableAutoConfiguration
@EntityScan(basePackageClasses=City.class)
public class Application {
    //...
}
```

73.5 Configure JPA properties

Spring Data JPA already provides some vendor-independent configuration options (e.g. for SQL logging) and Spring Boot exposes those, and a few more for hibernate as external configuration properties. The most common options to set are:

```
spring.jpa.hibernate.ddl-auto: create-drop
spring.jpa.hibernate.naming_strategy: org.hibernate.cfg.ImprovedNamingStrategy
spring.jpa.database: H2
spring.jpa.show-sql: true
```

(Because of relaxed data binding hyphens or underscores should work equally well as property keys.) The ddl-auto setting is a special case in that it has different defaults depending on whether you are using an embedded database (create-drop) or not (none). In addition all properties in spring.jpa.properties.* are passed through as normal JPA properties (with the prefix stripped) when the local EntityManagerFactory is created.

See HibernateJpaAutoConfiguration and JpaBaseConfiguration for more details.

73.6 Use a custom EntityManagerFactory

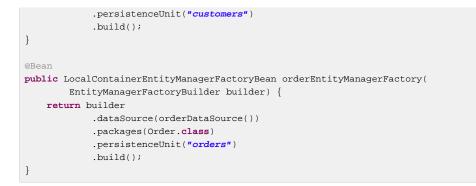

To take full control of the configuration of the EntityManagerFactory, you need to add a @Bean named 'entityManagerFactory'. Spring Boot auto-configuration switches off its entity manager based on the presence of a bean of that type.

73.7 Use Two EntityManagers

Even if the default EntityManagerFactory works fine, you will need to define a new one because otherwise the presence of the second bean of that type will switch off the default. To make it easy to do that you can use the convenient EntityManagerBuilder provided by Spring Boot, or if you prefer you can just use the LocalContainerEntityManagerFactoryBean directly from Spring ORM.

Example:

```
// add two data sources configured as above
@Bean
public LocalContainerEntityManagerFactoryBean customerEntityManagerFactory(
    EntityManagerFactoryBuilder builder) {
    return builder
        .dataSource(customerDataSource())
        .packages(Customer.class)
```

The configuration above almost works on its own. To complete the picture you need to configure TransactionManagers for the two EntityManagers as well. One of them could be picked up by the default JpaTransactionManager in Spring Boot if you mark it as @Primary. The other would have to be explicitly injected into a new instance. Or you might be able to use a JTA transaction manager spanning both.

If you are using Spring Data, you need to configure @EnableJpaRepositories accordingly:

73.8 Use a traditional persistence.xml

Spring doesn't require the use of XML to configure the JPA provider, and Spring Boot assumes you want to take advantage of that feature. If you prefer to use persistence.xml then you need to define your own @Bean of type LocalEntityManagerFactoryBean (with id 'entityManagerFactory', and set the persistence unit name there.

See $\underline{\tt JpaBaseConfiguration}$ for the default settings.

73.9 Use Spring Data JPA and Mongo repositories

Spring Data JPA and Spring Data Mongo can both create Repository implementations for you automatically. If they are both present on the classpath, you might have to do some extra configuration to tell Spring Boot which one (or both) you want to create repositories for you. The most explicit way to do that is to use the standard Spring Data @Enable*Repositories and tell it the location of your Repository interfaces (where '*' is 'Jpa' or 'Mongo' or both).

There are also flags spring.data.*.repositories.enabled that you can use to switch the autoconfigured repositories on and off in external configuration. This is useful for instance in case you want to switch off the Mongo repositories and still use the auto-configured MongoTemplate.

The same obstacle and the same features exist for other auto-configured Spring Data repository types (Elasticsearch, Solr). Just change the names of the annotations and flags respectively.

73.10 Expose Spring Data repositories as REST endpoint

Spring Data REST can expose the Repository implementations as REST endpoints for you as long as Spring MVC has been enabled for the application.

Spring Boot exposes as set of useful properties from the spring.data.rest namespace that customize the <u>RepositoryRestConfiguration</u>. If you need to provide additional customization, you should use a <u>RepositoryRestConfigurer</u> bean.

74. Database initialization

An SQL database can be initialized in different ways depending on what your stack is. Or of course you can do it manually as long as the database is a separate process.

74.1 Initialize a database using JPA

JPA has features for DDL generation, and these can be set up to run on startup against the database. This is controlled through two external properties:

- spring.jpa.generate-ddl (boolean) switches the feature on and off and is vendor independent.
- spring.jpa.hibernate.ddl-auto (enum) is a Hibernate feature that controls the behavior in a more fine-grained way. See below for more detail.

74.2 Initialize a database using Hibernate

You can set spring.jpa.hibernate.ddl-auto explicitly and the standard Hibernate property values are none, validate, update, create, create-drop. Spring Boot chooses a default value for you based on whether it thinks your database is embedded (default create-drop) or not (default none). An embedded database is detected by looking at the Connection type: hsqldb, h2 and derby are embedded, the rest are not. Be careful when switching from in-memory to a 'real' database that you don't make assumptions about the existence of the tables and data in the new platform. You either have to set ddl-auto explicitly, or use one of the other mechanisms to initialize the database.

Note

You can output the schema creation by enabling the org.hibernate.SQL logger. This is done for you automatically if you enable the <u>debug mode</u>.

In addition, a file named import.sql in the root of the classpath will be executed on startup. This can be useful for demos and for testing if you are careful, but probably not something you want to be on the classpath in production. It is a Hibernate feature (nothing to do with Spring).

74.3 Initialize a database using Spring JDBC

Spring JDBC has a DataSource initializer feature. Spring Boot enables it by default and loads SQL from the standard locations schema.sql and data.sql (in the root of the classpath). In addition Spring Boot will load the schema-\${platform}.sql and data-\${platform}.sql files (if present), where platform is the value of spring.datasource.platform, e.g. you might choose to set it to the vendor name of the database (hsqldb, h2, oracle, mysql, postgresql etc.). Spring Boot enables the fail-fast feature of the Spring JDBC initializer by default, so if the scripts cause exceptions the application will fail to start. The script locations can be changed by setting spring.datasource.schema and spring.datasource.data, and neither location will be processed if spring.datasource.initialize=false.

To disable the fail-fast you can set spring.datasource.continueOnError=true. This can be useful once an application has matured and been deployed a few times, since the scripts can act as 'poor man's migrations' — inserts that fail mean that the data is already there, so there would be no need to prevent the application from running, for instance.

If you want to use the schema.sql initialization in a JPA app (with Hibernate) then ddlauto=create-drop will lead to errors if Hibernate tries to create the same tables. To avoid those errors set ddl-auto explicitly to "" (preferable) or "none". Whether or not you use ddl-auto=createdrop you can always use data.sql to initialize new data.

74.4 Initialize a Spring Batch database

If you are using Spring Batch then it comes pre-packaged with SQL initialization scripts for most popular database platforms. Spring Boot will detect your database type, and execute those scripts by default, and in this case will switch the fail fast setting to false (errors are logged but do not prevent the application from starting). This is because the scripts are known to be reliable and generally do not contain bugs, so errors are ignorable, and ignoring them makes the scripts idempotent. You can switch off the initialization explicitly using spring.batch.initializer.enabled=false.

74.5 Use a higher level database migration tool

Spring Boot works fine with higher level migration tools <u>Flyway</u> (SQL-based) and <u>Liquibase</u> (XML). In general we prefer Flyway because it is easier on the eyes, and it isn't very common to need platform independence: usually only one or at most couple of platforms is needed.

Execute Flyway database migrations on startup

To automatically run Flyway database migrations on startup, add the org.flywaydb:flyway-core to your classpath.

The migrations are scripts in the form V<VERSION>__<NAME>.sql (with <VERSION> an underscoreseparated version, e.g. '1' or '2_1'). By default they live in a folder classpath:db/migration but you can modify that using flyway.locations (a list). See the Flyway class from flyway-core for details of available settings like schemas etc. In addition Spring Boot provides a small set of properties in FlywayProperties that can be used to disable the migrations, or switch off the location checking.

Тір

If you want to make use of <u>Flyway callbacks</u>, those scripts should also live in the classpath:db/migration folder.

By default Flyway will autowire the (@Primary) DataSource in your context and use that for migrations. If you like to use a different DataSource you can create one and mark its @Bean as @FlywayDataSource - if you do that remember to create another one and mark it as @Primary if you want two data sources. Or you can use Flyway's native DataSource by setting flyway. [url,user,password] in external properties.

There is a <u>Flyway sample</u> so you can see how to set things up.

Execute Liquibase database migrations on startup

To automatically run Liquibase database migrations on startup, add the org.liquibase:liquibase-core to your classpath.

The master change log is by default read from db/changelog/db.changelog-master.yaml but can be set using liquibase.change-log. See <u>LiquibaseProperties</u> for details of available settings like contexts, default schema etc.

There is a <u>Liquibase sample</u> so you can see how to set things up.

75. Batch applications

75.1 Execute Spring Batch jobs on startup

Spring Batch auto-configuration is enabled by adding @EnableBatchProcessing (from Spring Batch) somewhere in your context.

By default it executes **all** Jobs in the application context on startup (see <u>JobLauncherCommandLineRunner</u> for details). You can narrow down to a specific job or jobs by specifying spring.batch.job.names (comma-separated job name patterns).

If the application context includes a JobRegistry then the jobs in spring.batch.job.names are looked up in the registry instead of being autowired from the context. This is a common pattern with more complex systems where multiple jobs are defined in child contexts and registered centrally.

See <u>BatchAutoConfiguration</u> and <u>@EnableBatchProcessing</u> for more details.

76. Actuator

76.1 Change the HTTP port or address of the actuator endpoints

In a standalone application the Actuator HTTP port defaults to the same as the main HTTP port. To make the application listen on a different port set the external property management.port. To listen on a completely different network address (e.g. if you have an internal network for management and an external one for user applications) you can also set management.address to a valid IP address that the server is able to bind to.

For more detail look at the <u>ManagementServerProperties</u> source code and <u>Section 46.3</u>, <u>"Customizing the management server port"</u> in the 'Production-ready features' section.

76.2 Customize the 'whitelabel' error page

Spring Boot installs a 'whitelabel' error page that you will see in browser client if you encounter a server error (machine clients consuming JSON and other media types should see a sensible response with the right error code). To switch it off you can set server.error.whitelabel.enabled=false, but normally in addition or alternatively to that you will want to add your own error page replacing the whitelabel one. Exactly how you do this depends on the templating technology that you are using. For example, if you are using Thymeleaf you would add an error.html template and if you are using FreeMarker you would add an error.ftl template. In general what you need is a View that resolves with a name of error, and/or a @Controller that handles the /error path. Unless you replaced some of the default configuration you should find a BeanNameViewResolver in your ApplicationContext so a @Bean with id error would be a simple way of doing that. Look at ErrorMvcAutoConfiguration for more options.

See also the section on Error Handling for details of how to register handlers in the servlet container.

76.3 Actuator and Jersey

Actuator HTTP endpoints are only available for Spring MVC-based applications. If you want to use Jersey and still use the actuator you will need to enable Spring MVC (by depending on spring-boot-starter-web, for example). By default, both Jersey and the Spring MVC dispatcher servlet are mapped to the same path (/). You will need to change the path for one of them (by configuring server.servlet-path for Spring MVC or spring.jersey.application-path for Jersey). For example, if you add server.servlet-path=/system into application.properties, the actuator HTTP endpoints will be available under /system.

77. Security

77.1 Switch off the Spring Boot security configuration

If you define a @Configuration with @EnableWebSecurity anywhere in your application it will switch off the default webapp security settings in Spring Boot. To tweak the defaults try setting properties in security.* (see <u>SecurityProperties</u> for details of available settings) and <u>SECURITY</u> section of <u>Common application properties</u>.

77.2 Change the AuthenticationManager and add user accounts

If you provide a @Bean of type AuthenticationManager the default one will not be created, so you have the full feature set of Spring Security available (e.g. <u>various authentication options</u>).

Spring Security also provides a convenient AuthenticationManagerBuilder which can be used to build an AuthenticationManager with common options. The recommended way to use this in a webapp is to inject it into a void method in a WebSecurityConfigurerAdapter, e.g.

```
@Configuration
public class SecurityConfiguration extends WebSecurityConfigurerAdapter {
    @Autowired
    public void configureGlobal(AuthenticationManagerBuilder auth) throws Exception {
        auth.inMemoryAuthentication()
        .withUser("barry").password("password").roles("USER"); // ... etc.
    }
    // ... other stuff for application security
}
```

You will get the best results if you put this in a nested class, or a standalone class (i.e. not mixed in with a lot of other @Beans that might be allowed to influence the order of instantiation). The secure web sample is a useful template to follow.

If you experience instantiation issues (e.g. using JDBC or JPA for the user detail store) it might be worth extracting the AuthenticationManagerBuilder callback into a GlobalAuthenticationConfigurerAdapter (in the init() method so it happens before the authentication manager is needed elsewhere), e.g.

```
@Configuration
public class AuthenticationManagerConfiguration extends
    GlobalAuthenticationConfigurerAdapter {
    @Override
    public void init(AuthenticationManagerBuilder auth) {
        auth.inMemoryAuthentication() // ... etc.
    }
}
```

77.3 Enable HTTPS when running behind a proxy server

Ensuring that all your main endpoints are only available over HTTPS is an important chore for any application. If you are using Tomcat as a servlet container, then Spring Boot will add Tomcat's own

RemoteIpValve automatically if it detects some environment settings, and you should be able to rely on the HttpServletRequest to report whether it is secure or not (even downstream of a proxy server that handles the real SSL termination). The standard behavior is determined by the presence or absence of certain request headers (x-forwarded-for and x-forwarded-proto), whose names are conventional, so it should work with most front end proxies. You can switch on the valve by adding some entries to application.properties, e.g.

```
server.tomcat.remote_ip_header=x-forwarded-for
server.tomcat.protocol_header=x-forwarded-proto
```

(The presence of either of those properties will switch on the valve. Or you can add the RemoteIpValve yourself by adding a TomcatEmbeddedServletContainerFactory bean.)

Spring Security can also be configured to require a secure channel for all (or some requests). To switch that on in a Spring Boot application you just need to set security.require_ssl to true in application.properties.

78. Hot swapping

78.1 Reload static content

There are several options for hot reloading. The recommended approach is to use <u>spring-boot-</u> <u>devtools</u> as it provides additional development-time features such as support for fast application restarts and LiveReload as well as sensible development-time configuration (e.g. template caching).

Alternatively, running in an IDE (especially with debugging on) is a good way to do development (all modern IDEs allow reloading of static resources and usually also hot-swapping of Java class changes).

Finally, the <u>Maven and Gradle plugins</u> can be configured (see the addResources property) to support running from the command line with reloading of static files. You can use that with an external css/js compiler process if you are writing that code with higher level tools.

78.2 Reload templates without restarting the container

Most of the templating technologies supported by Spring Boot include a configuration option to disable caching (see below for details). If you're using the spring-boot-devtools module these properties will be <u>automatically configured</u> for you at development time.

Thymeleaf templates

If you are using Thymeleaf, then set spring.thymeleaf.cache to false. See ThymeleafAutoConfiguration for other Thymeleaf customization options.

FreeMarker templates

If you are using FreeMarker, then set spring.freemarker.cache to false. See FreeMarkerAutoConfiguration for other FreeMarker customization options.

Groovy templates

If you are using Groovy templates, then set spring.groovy.template.cache to false. See <u>GroovyTemplateAutoConfiguration</u> for other Groovy customization options.

Velocity templates

If you are using Velocity, then set spring.velocity.cache to false. See <u>VelocityAutoConfiguration</u> for other Velocity customization options.

78.3 Fast application restarts

The spring-boot-devtools module includes support for automatic application restarts. Whilst not as fast a technologies such as <u>JRebel</u> or <u>Spring Loaded</u> it's usually significantly faster than a "cold start". You should probably give it a try before investigating some of the more complex reload options discussed below.

For more details see the <u>Chapter 20</u>, <u>Developer tools</u> section.

78.4 Reload Java classes without restarting the container

Modern IDEs (Eclipse, IDEA, etc.) all support hot swapping of bytecode, so if you make a change that doesn't affect class or method signatures it should reload cleanly with no side effects.

<u>Spring Loaded</u> goes a little further in that it can reload class definitions with changes in the method signatures. With some customization it can force an ApplicationContext to refresh itself (but there is no general mechanism to ensure that would be safe for a running application anyway, so it would only ever be a development time trick probably).

Configuring Spring Loaded for use with Maven

To use Spring Loaded with the Maven command line, just add it as a dependency in the Spring Boot plugin declaration, e.g.

```
<plugin>
<groupId>org.springframework.boot</groupId>
<artifactId>spring-boot-maven-plugin</artifactId>
<dependencies>
<dependency>
<groupId>org.springframework</groupId>
<artifactId>springloaded</artifactId>
</dependency>
</dependency>
</dependency>
</dependency>
</dependencies>
</plugin>
```

This normally works pretty well with Eclipse and IntelliJ IDEA as long as they have their build configuration aligned with the Maven defaults (Eclipse m2e does this out of the box).

Configuring Spring Loaded for use with Gradle and IntelliJ IDEA

You need to jump through a few hoops if you want to use Spring Loaded in combination with Gradle and IntelliJ IDEA. By default, IntelliJ IDEA will compile classes into a different location than Gradle, causing Spring Loaded monitoring to fail.

To configure IntelliJ IDEA correctly you can use the idea Gradle plugin:

```
buildscript {
   repositories { jcenter() }
   dependencies {
      classpath "org.springframework.boot:spring-boot-gradle-plugin:1.3.3.RELEASE"
      classpath 'org.springframework:springloaded:1.2.0.RELEASE'
   }
}
apply plugin: 'idea'
idea {
   module {
      inheritOutputDirs = false
      outputDir = file("$buildDir/classes/main/")
   }
}
// ...
```

Note

IntelliJ IDEA must be configured to use the same Java version as the command line Gradle task and springloaded **must** be included as a buildscript dependency.

You can also additionally enable 'Make Project Automatically' inside IntelliJ IDEA to automatically compile your code whenever a file is saved.

79. Build

79.1 Customize dependency versions

If you use a Maven build that inherits directly or indirectly from spring-boot-dependencies (for instance spring-boot-starter-parent) but you want to override a specific third-party dependency you can add appropriate <properties> elements. Browse the <properties_boot-dependencies POM for a complete list of properties. For example, to pick a different <pre>slf4j version you would add the following:

```
<properties>
<slf4j.version>1.7.5<slf4j.version>
</properties>
```

Note

This only works if your Maven project inherits (directly or indirectly) from springboot-dependencies. If you have added spring-boot-dependencies in your own dependencyManagement section with <scope>import</scope> you have to redefine the artifact yourself instead of overriding the property.

Warning

Each Spring Boot release is designed and tested against a specific set of third-party dependencies. Overriding versions may cause compatibility issues.

To override dependency versions in Gradle, you can specify a version as shown below:

ext['slf4j.version'] = '1.7.5'

For additional information, please refer to the Gradle Dependency Management Plugin documentation.

79.2 Create an executable JAR with Maven

The spring-boot-maven-plugin can be used to create an executable 'fat' JAR. If you are using the spring-boot-starter-parent POM you can simply declare the plugin and your jars will be repackaged:

If you are not using the parent POM you can still use the plugin, however, you must additionally add an <executions> section:

```
<br/><build>
<plugins>
<plugin>
<groupId>org.springframework.boot</groupId>
<artifactId>spring-boot-maven-plugin</artifactId>
<version>1.3.3.RELEASE</version>
```

```
<executions>
<executions>
<goals>
<goal>repackage</goal>
</goals>
</execution>
</executions>
</plugins>
</plugins>
</build>
```

See the plugin documentation for full usage details.

79.3 Create an additional executable JAR

If you want to use your project as a library jar for other projects to depend on, and in addition have an executable (e.g. demo) version of it, you will want to configure the build in a slightly different way.

For Maven the normal JAR plugin and the Spring Boot plugin both have a 'classifier' configuration that you can add to create an additional JAR. Example (using the Spring Boot Starter Parent to manage the plugin versions and other configuration defaults):

```
<build>
<plugins>
<plugins>
<groupId>org.springframework.boot</groupId>
<artifactId>spring-boot-maven-plugin</artifactId>
<configuration>
<classifier>exec</classifier>
</configuration>
</plugin>
</plugins>
</build>
```

Two jars are produced, the default one, and an executable one using the Boot plugin with classifier 'exec'.

For Gradle users the steps are similar. Example:

```
bootRepackage {
    classifier = 'exec'
}
```

79.4 Extract specific libraries when an executable jar runs

Most nested libraries in an executable jar do not need to be unpacked in order to run, however, certain libraries can have problems. For example, JRuby includes its own nested jar support which assumes that the jruby-complete.jar is always directly available as a file in its own right.

To deal with any problematic libraries, you can flag that specific nested jars should be automatically unpacked to the 'temp folder' when the executable jar first runs.

For example, to indicate that JRuby should be flagged for unpack using the Maven Plugin you would add the following configuration:

And to do that same with Gradle:

```
springBoot {
    requiresUnpack = ['org.jruby:jruby-complete']
}
```

79.5 Create a non-executable JAR with exclusions

Often if you have an executable and a non-executable jar as build products, the executable version will have additional configuration files that are not needed in a library jar. E.g. the application.yml configuration file might excluded from the non-executable JAR.

Here's how to do that in Maven:

```
<build>
   <plugins>
       <plugin>
            <groupId>org.springframework.boot</groupId>
            <artifactId>spring-boot-maven-plugin</artifactId>
            <configuration>
               <classifier>exec</classifier>
            </configuration>
       </plugin>
        <plugin>
            <artifactId>maven-jar-plugin</artifactId>
            <executions>
                <execution>
                    <id>exec</id>
                    <phase>package</phase>
                    <goals>
                       <goal>jar</goal>
                    </goals>
                    <configuration>
                       <classifier>exec</classifier>
                    </configuration>
                </execution>
                <execution>
                    <phase>package</phase>
                    <goals>
                       <goal>jar</goal>
                    </goals>
                    <configuration>
                       <!-- Need this to ensure application.yml is excluded -->
                        <forceCreation>true</forceCreation>
                        <excludes>
                            <exclude>application.yml</exclude>
                        </excludes>
                    </configuration>
                </execution>
            </executions>
        </plugin>
    </plugins>
</build>
```

In Gradle you can create a new JAR archive with standard task DSL features, and then have the bootRepackage task depend on that one using its withJarTask property:

```
jar {
   baseName = 'spring-boot-sample-profile'
   version = '0.0.0'
   excludes = ['**/application.yml']
}
task('execJar', type:Jar, dependsOn: 'jar') {
   baseName = 'spring-boot-sample-profile'
   version = '0.0.0'
   classifier = 'exec'
   from sourceSets.main.output
}
bootRepackage {
   withJarTask = tasks['execJar']
}
```

79.6 Remote debug a Spring Boot application started with Maven

To attach a remote debugger to a Spring Boot application started with Maven you can use the jvmArguments property of the maven plugin.

Check this example for more details.

79.7 Remote debug a Spring Boot application started with Gradle

To attach a remote debugger to a Spring Boot application started with Gradle you can use the applicationDefaultJvmArgs in build.gradle or --debug-jvm command line option.

build.gradle:

```
applicationDefaultJvmArgs = [
    "-agentlib:jdwp=transport=dt_socket,server=y,suspend=y,address=5005"
]
```

Command line:

\$ gradle run --debug-jvm

Check Gradle Application Plugin for more details.

79.8 Build an executable archive from Ant without using spring-boot-antlib

To build with Ant you need to grab dependencies, compile and then create a jar or war archive as normal. To make it executable you can either use the spring-boot-antlib module, or you can follow these instructions:

- 1. Use the appropriate launcher as a Main-Class, e.g. JarLauncher for a jar file, and specify the other properties it needs as manifest entries, principally a Start-Class.
- 2. Add the runtime dependencies in a nested 'lib' directory (for a jar) and the provided (embedded container) dependencies in a nested lib-provided directory. Remember **not** to compress the entries in the archive.

3. Add the spring-boot-loader classes at the root of the archive (so the Main-Class is available).

Example:

```
<target name="build" depends="compile">
<copy todir="target/classes/lib">
<fileset dir="lib/runtime" />
</copy>
<jar destfile="target/spring-boot-sample-actuator-${spring-boot.version}.jar" compress="false">
<fileset dir="target/classes" />
<fileset dir="src/main/resources" />
<fileset dir="src/main/resources" />
<fileset src="lib/loader/spring-boot-loader-jar-${spring-boot.version}.jar" />
<manifest>
<attribute name="Main-Class" value="org.springframework.boot.loader.JarLauncher" />
<attribute name="Start-Class" value="${start-class}" />
</manifest>
</jar>
```

The Actuator Sample has a build.xml that should work if you run it with

\$ ant -lib <folder containing ivy-2.2.jar>

after which you can run the application with

\$ java -jar target/*.jar

79.9 How to use Java 6

If you want to use Spring Boot with Java 6 there are a small number of configuration changes that you will have to make. The exact changes depend on your application's functionality.

Embedded servlet container compatibility

If you are using one of Boot's embedded Servlet containers you will have to use a Java 6-compatible container. Both Tomcat 7 and Jetty 8 are Java 6 compatible. See <u>Section 70.15</u>, "Use Tomcat 7" and <u>Section 70.16</u>, "Use Jetty 8" for details.

JTA API compatibility

While the Java Transaction API itself doesn't require Java 7 the official API jar contains classes that have been built to require Java 7. If you are using JTA then you will need to replace the official JTA 1.2 API jar with one that has been built to work on Java 6. To do so, exclude any transitive dependencies on javax.transaction:javax.transaction-api and replace them with a dependency on org.jboss.spec.javax.transaction:jboss-transaction-api_1.2_spec:1.0.0.Final

80. Traditional deployment

80.1 Create a deployable war file

The first step in producing a deployable war file is to provide a SpringBootServletInitializer subclass and override its configure method. This makes use of Spring Framework's Servlet 3.0 support and allows you to configure your application when it's launched by the servlet container. Typically, you update your application's main class to extend SpringBootServletInitializer:

The next step is to update your build configuration so that your project produces a war file rather than a jar file. If you're using Maven and using spring-boot-starter-parent (which configures Maven's war plugin for you) all you need to do is modify pom.xml to change the packaging to war:

<packaging>war</packaging>

If you're using Gradle, you need to modify build.gradle to apply the war plugin to the project:

apply plugin: 'war'

The final step in the process is to ensure that the embedded servlet container doesn't interfere with the servlet container to which the war file will be deployed. To do so, you need to mark the embedded servlet container dependency as provided.

If you're using Maven:

And if you're using Gradle:

If you're using the <u>Spring Boot build tools</u>, marking the embedded servlet container dependency as provided will produce an executable war file with the provided dependencies packaged in a lib-

provided directory. This means that, in addition to being deployable to a servlet container, you can also run your application using java -jar on the command line.

Тір

Take a look at Spring Boot's sample applications for a <u>Maven-based example</u> of the abovedescribed configuration.

80.2 Create a deployable war file for older servlet containers

Older Servlet containers don't have support for the ServletContextInitializer bootstrap process used in Servlet 3.0. You can still use Spring and Spring Boot in these containers but you are going to need to add a web.xml to your application and configure it to load an ApplicationContext via a DispatcherServlet.

80.3 Convert an existing application to Spring Boot

For a non-web application it should be easy (throw away the code that creates your ApplicationContext and replace it with calls to SpringApplication or SpringApplicationBuilder). Spring MVC web applications are generally amenable to first creating a deployable war application, and then migrating it later to an executable war and/or jar. Useful reading is in the <u>Getting Started Guide on Converting a jar to a war</u>.

Create a deployable war by extending SpringBootServletInitializer (e.g. in a class called Application), and add the Spring Boot @EnableAutoConfiguration annotation. Example:

```
@Configuration
@EnableAutoConfiguration
@ComponentScan
public class Application extends SpringBootServletInitializer {
    @Override
    protected SpringApplicationBuilder configure(SpringApplicationBuilder application) {
        // Customize the application or call application.sources(...) to add sources
        // Since our example is itself a @Configuration class we actually don't
        // need to override this method.
        return application;
    }
}
```

Remember that whatever you put in the sources is just a Spring ApplicationContext and normally anything that already works should work here. There might be some beans you can remove later and let Spring Boot provide its own defaults for them, but it should be possible to get something working first.

Static resources can be moved to /public (or /static or /resources or /META-INF/resources) in the classpath root. Same for messages.properties (Spring Boot detects this automatically in the root of the classpath).

Vanilla usage of Spring DispatcherServlet and Spring Security should require no further changes. If you have other features in your application, using other servlets or filters for instance, then you may need to add some configuration to your Application context, replacing those elements from the web.xml as follows:

• A @Bean of type Servlet or ServletRegistrationBean installs that bean in the container as if it was a <servlet/> and <servlet-mapping/> in web.xml.

- A @Bean of type Filter or FilterRegistrationBean behaves similarly (like a <filter/> and <filter-mapping/>.
- An ApplicationContext in an XML file can be added to an @Import in your Application. Or simple cases where annotation configuration is heavily used already can be recreated in a few lines as @Bean definitions.

Once the war is working we make it executable by adding a main method to our Application, e.g.

```
public static void main(String[] args) {
    SpringApplication.run(Application.class, args);
}
```

Applications can fall into more than one category:

- Servlet 3.0+ applications with no web.xml.
- Applications with a web.xml.
- Applications with a context hierarchy.
- Applications without a context hierarchy.

All of these should be amenable to translation, but each might require slightly different tricks.

Servlet 3.0+ applications might translate pretty easily if they already use the Spring Servlet 3.0+ initializer support classes. Normally all the code from an existing WebApplicationInitializer can be moved into a SpringBootServletInitializer. If your existing application has more than one ApplicationContext (e.g. if it uses AbstractDispatcherServletInitializer) then you might be able to squash all your context sources into a single SpringApplication. The main complication you might encounter is if that doesn't work and you need to maintain the context hierarchy. See the <u>entry on building a hierarchy</u> for examples. An existing parent context that contains web-specific features will usually need to be broken up so that all the ServletContextAware components are in the child context.

Applications that are not already Spring applications might be convertible to a Spring Boot application, and the guidance above might help, but your mileage may vary.

80.4 Deploying a WAR to WebLogic

To deploy a Spring Boot application to WebLogic you must ensure that your servlet initializer **directly** implements WebApplicationInitializer (even if you extend from a base class that already implements it).

A typical initializer for WebLogic would be something like this:

```
import org.springframework.boot.autoconfigure.SpringBootApplication;
import org.springframework.boot.context.web.SpringBootServletInitializer;
import org.springframework.web.WebApplicationInitializer;
@SpringBootApplication
public class MyApplication extends SpringBootServletInitializer implements WebApplicationInitializer {
}
```

If you use logback, you will also need to tell WebLogic to prefer the packaged version rather than the version that pre-installed with the server. You can do this by adding a WEB-INF/weblogic.xml file with the following contents:

80.5 Deploying a WAR in an Old (Servlet 2.5) Container

Spring Boot uses Servlet 3.0 APIs to initialize the ServletContext (register Servlets etc.) so you can't use the same application out of the box in a Servlet 2.5 container. It **is** however possible to run a Spring Boot application on an older container with some special tools. If you include org.springframework.boot:spring-boot-legacy as a dependency (maintained separately to the core of Spring Boot and currently available at 1.0.0.RELEASE), all you should need to do is create a web.xml and declare a context listener to create the application context and your filters and servlets. The context listener is a special purpose one for Spring Boot, but the rest of it is normal for a Spring application in Servlet 2.5. Example:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app version="2.5" xmlns="http://java.sun.com/xml/ns/javaee"</pre>
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation="http://java.sun.com/xml/ns/javaee http://java.sun.com/xml/ns/javaee/web-
app_2_5.xsd">
    <context-param>
       <param-name>contextConfigLocation</param-name>
       <param-value>demo.Application</param-value>
    </context-param>
    <listener>
       <listener-class>org.springframework.boot.legacy.context.web.SpringBootContextLoaderListener
listener-class>
    </listener>
    <filter>
        <filter-name>metricFilter</filter-name>
        <filter-class>org.springframework.web.filter.DelegatingFilterProxy</filter-class>
    </filter>
    <filter-mapping>
       <filter-name>metricFilter</filter-name>
        <url-pattern>/*</url-pattern>
    </filter-mapping>
    <servlet>
       <servlet-name>appServlet</servlet-name>
        <servlet-class>org.springframework.web.servlet.DispatcherServlet</servlet-class>
        <init-param>
           <param-name>contextAttribute</param-name>
            <param-value>org.springframework.web.context.WebApplicationContext.ROOT</param-value>
        </init-param>
        <load-on-startup>1</load-on-startup>
    </servlet>
    <servlet-mapping>
        <servlet-name>appServlet</servlet-name>
       <url-pattern>/</url-pattern>
    </servlet-mapping>
```

</web-app>

In this example we are using a single application context (the one created by the context listener) and attaching it to the DispatcherServlet using an init parameter. This is normal in a Spring Boot application (you normally only have one application context).

Part X. Appendices

Appendix A. Common application properties

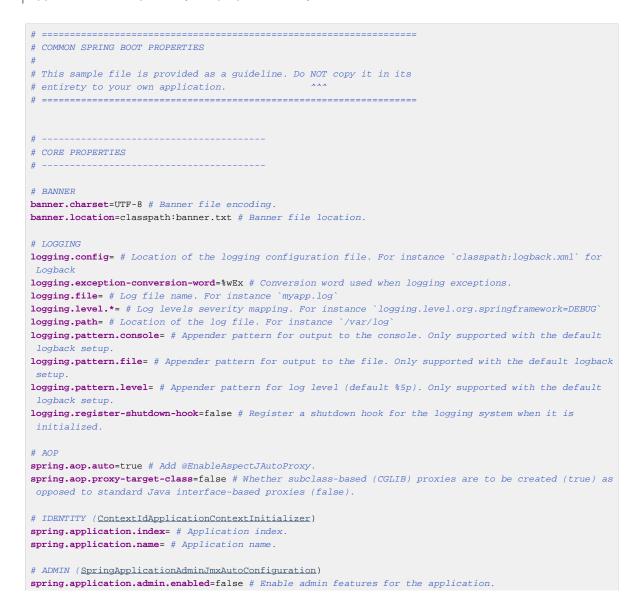

Various properties can be specified inside your application.properties/application.yml file or as command line switches. This section provides a list common Spring Boot properties and references to the underlying classes that consume them.

Note

Property contributions can come from additional jar files on your classpath so you should not consider this an exhaustive list. It is also perfectly legit to define your own properties.

Warning

This sample file is meant as a guide only. Do **not** copy/paste the entire content into your application; rather pick only the properties that you need.

spring.application.admin.jmx-name=org.springframework.boot:type=Admin,name=SpringApplication # JMX name of the application admin MBean. # AUTO-CONFIGURATION spring.autoconfigure.exclude= # Auto-configuration classes to exclude. # SPRING CORE spring.beaninfo.ignore=true # Skip search of BeanInfo classes. # SPRING CACHE (CacheProperties) spring.cache.cache-names= # Comma-separated list of cache names to create if supported by the underlying cache manager. spring.cache.ehcache.config= # The location of the configuration file to use to initialize EhCache. spring.cache.guava.spec= # The spec to use to create caches. Appendix B. Configuration meta-data

Spring Boot jars are shipped with meta-data files that provide details of all supported configuration properties. The files are designed to allow IDE developers to offer contextual help and "code completion" as users are working with application.properties or application.yml files.

The majority of the meta-data file is generated automatically at compile time by processing all items annotated with @ConfigurationProperties. However, it is possible to <u>write part of the meta-data</u> <u>manually</u> for corner cases or more advanced use cases.

B.1 Meta-data format

Configuration meta-data files are located inside jars under META-INF/spring-configurationmetadata.json They use a simple JSON format with items categorized under either "groups" or "properties" and additional values hint categorized under "hints":

```
{"groups": [
   {
        "name": "server",
        "type": "org.springframework.boot.autoconfigure.web.ServerProperties",
       "sourceType": "org.springframework.boot.autoconfigure.web.ServerProperties"
   },
    {
       "name": "spring.jpa.hibernate",
       "type": "org.springframework.boot.autoconfigure.orm.jpa.JpaProperties$Hibernate",
        "sourceType": "org.springframework.boot.autoconfigure.orm.jpa.JpaProperties",
        "sourceMethod": "getHibernate()"
   }
],"properties": [
   {
       "name": "server.port",
       "type": "java.lang.Integer",
        "sourceType": "org.springframework.boot.autoconfigure.web.ServerProperties"
   },
   {
       "name": "server.servlet-path",
       "type": "java.lang.String",
        "sourceType": "org.springframework.boot.autoconfigure.web.ServerProperties",
       "defaultValue": "/"
   },
    {
         "name": "spring.jpa.hibernate.ddl-auto",
         "type": "java.lang.String",
          "description": "DDL mode. This is actually a shortcut for the \"hibernate.hbm2ddl.auto\"
property.",
          "sourceType": "org.springframework.boot.autoconfigure.orm.jpa.JpaProperties$Hibernate"
   }
],"hints": [
   {
       "name": "spring.jpa.hibernate.ddl-auto",
        "values": [
           {
                "value": "none",
               "description": "Disable DDL handling."
           },
            {
                "value": "validate",
                "description": "Validate the schema, make no changes to the database."
           },
            {
                "value": "update",
                "description": "Update the schema if necessary."
```

Each "property" is a configuration item that the user specifies with a given value. For example server.port and server.servlet-path might be specified in application.properties as follows:

server.port=9090
server.servlet-path=/home

The "groups" are higher level items that don't themselves specify a value, but instead provide a contextual grouping for properties. For example the server.port and server.servlet-path properties are part of the server group.

Note

It is not required that every "property" has a "group", some properties might just exist in their own right.

Finally, "hints" are additional information used to assist the user in configuring a given property. When configuring the spring.jpa.hibernate.ddl-auto property, a tool can use it to offer some auto-completion help for the none, validate, update, create and create-drop values.

Group Attributes

The JSON object contained in the groups array can contain the following attributes:

Name	Туре	Purpose	
name	String	The full name of the group. This attribute is mandatory.	
type	String	The class name of the data type of the group. For example, if the group was based on a class annotated with @ConfigurationProperties the attribute would contain the fully qualified name of that class. If it was based on a @Bean method, it would be the return type of that method. The attribute may be omitted if the type is not known.	
description	String	A short description of the group that can be displayed to users. May be omitted if no description is available. It is recommended that descriptions are a short paragraphs, with the first line providing a concise summary. The last line in the description should end with a period (.).	
sourceType	String	The class name of the source that contributed this group. For example, if the group was based on a @Bean method annotated	

Name	Туре	Purpose	
		with @ConfigurationProperties this attribute would contain the fully qualified name of the @Configuration class containing the method. The attribute may be omitted if the source type is not known.	
sourceMethoo	1 String	The full name of the method (include parenthesis and argument types) that contributed this group. For example, the name of a @ConfigurationProperties annotated @Bean method. May be omitted if the source method is not known.	

Property Attributes

The JSON object contained in the properties array can contain the following attributes:

Name	Туре	Purpose
name	String	The full name of the property. Names are in lowercase dashed form (e.g. server.servlet-path). This attribute is mandatory.
type	String	The class name of the data type of the property. For example, java.lang.String. This attribute can be used to guide the user as to the types of values that they can enter. For consistency, the type of a primitive is specified using its wrapper counterpart, i.e. boolean becomes java.lang.Boolean. Note that this class may be a complex type that gets converted from a String as values are bound. May be omitted if the type is not known.
description	String	A short description of the group that can be displayed to users. May be omitted if no description is available. It is recommended that descriptions are a short paragraphs, with the first line providing a concise summary. The last line in the description should end with a period (.).
sourceType	String	The class name of the source that contributed this property. For example, if the property was from a class annotated with @ConfigurationProperties this attribute would contain the fully qualified name of that class. May be omitted if the source type is not known.
defaultValue	e Object	The default value which will be used if the property is not specified. Can also be an array of value(s) if the type of the property is an array. May be omitted if the default value is not known.
deprecation	Deprecation	Specify if the property is deprecated. May be omitted if the field is not deprecated or if that information is not known. See below for more details.

The JSON object contained in the deprecation attribute of each properties element can contain the following attributes:

Name	Туре	Purpose
reason	String	A short description of the reason why the property was deprecated. May be omitted if no reason is available. It is recommended that descriptions are a short paragraphs, with the first line providing a concise summary. The last line in the description should end with a period (.).
replacement	String	The full name of the property that is <i>replacing</i> this deprecated property. May be omitted if there is no replacement for this property.

Note

Prior to Spring Boot 1.3, a single deprecated boolean attribute can be used instead of the deprecation element. This is still supported in a deprecated fashion and should no longer be used. If no reason and replacement are available, an empty deprecation object should be set.

Deprecation can also be specified declaratively in code by adding the @DeprecatedConfigurationProperty annotation to the getter exposing the deprecated property. For instance, let's assume the app.foo.target property was confusing and was renamed to app.foo.name

```
@ConfigurationProperties("app.foo")
public class FooProperties {
    private String name;
    public String getName() { ... }
    public void setName(String name) { ... }
    @DeprecatedConfigurationProperty(replacement = "app.foo.name")
    @Deprecated
    public String getTarget() {
        return getName();
    }
    @Deprecated
    public void setTarget(String target) {
        setName(target);
    }
}
```

The code above makes sure that the deprecated property still works (delegating to the name property behind the scenes). Once the getTarget and setTarget methods can be removed from your public API, the automatic deprecation hint in the meta-data will go away as well.

Hint Attributes

The JSON object contained in the hints array can contain the following attributes:

Name	Туре	Purpose
name	String	The full name of the property that this hint refers to. Names are in lowercase dashed form (e.g. server.servlet-path). If the property refers to a map (e.g. system.contexts) the hint either

Name	Туре	Purpose	
		applies to the <i>keys</i> of the map (system.context.keys) or the values (system.context.values). This attribute is mandatory.	
values	ValueHint[]	A list of valid values as defined by the ValueHint object (see below). Each entry defines the value and may have a description	
providers	ValueProvider[]	A list of providers as defined by the ValueProvider object (see below). Each entry defines the name of the provider and its parameters, if any.	

The JSON object contained in the values attribute of each hint element can contain the following attributes:

Name	Туре	Purpose	
value	Object	A valid value for the element to which the hint refers to. Can also be an array of value(s) if the type of the property is an array. This attribute is mandatory.	
description	String	A short description of the value that can be displayed to users. May be omitted if no description is available. It is recommended that descriptions are a short paragraphs, with the first line providing a concise summary. The last line in the description should end with a period (.).	

The JSON object contained in the providers attribute of each hint element can contain the following attributes:

Name	Туре	Purpose	
name	String	The name of the provider to use to offer additional content assistance for the element to which the hint refers to.	
parameters	JSON object	Any additional parameter that the provider supports (check the documentation of the provider for more details).	

Repeated meta-data items

It is perfectly acceptable for "property" and "group" objects with the same name to appear multiple times within a meta-data file. For example, Spring Boot binds <code>spring.datasource</code> properties to Hikari, Tomcat and DBCP classes, with each potentially offering overlap of property names. Consumers of meta-data should take care to ensure that they support such scenarios.

B.2 Providing manual hints

To improve the user experience and further assist the user in configuring a given property, you can provide additional meta-data that:

- 1. Describes the list of potential values for a property.
- 2. Associates a provider to attach a well-defined semantic to a property so that a tool can discover the list of potential values based on the project's context.

Value hint

The name attribute of each hint refers to the name of a property. In the initial example above, we provide 5 values for the spring.jpa.hibernate.ddl-auto property: none, validate, update, create and create-drop. Each value may have a description as well.

If your property is of type Map, you can provide hints for both the keys and the values (but not for the map itself). The special .keys and .values suffixes must be used to refer to the keys and the values respectively.

Let's assume a foo.contexts that maps magic String values to an integer:

```
@ConfigurationProperties("foo")
public class FooProperties {
    private Map<String,Integer> contexts;
    // getters and setters
}
```

The magic values are foo and bar for instance. In order to offer additional content assistance for the keys, you could add the following to the manual meta-data of the module:

Note

Of course, you should have an Enum for those two values instead. This is by far the most effective approach to auto-completion if your IDE supports it.

Value provider

Providers are a powerful way of attaching semantics to a property. We define in the section below the official providers that you can use for your own hints. Bare in mind however that your favorite IDE may implement some of these or none of them. It could eventually provide its own as well.

Note

As this is a new feature, IDE vendors will have to catch up with this new feature.

The table below summarizes the list of supported providers:

Name	Description
any	Permit any additional value to be provided.

Name	Description
class-reference	Auto-complete the classes available in the project. Usually constrained by a base class that is specified via the target parameter.
handle-as	Handle the property as if it was defined by the type defined via the mandatory target parameter.
logger-name	Auto-complete valid logger names. Typically, package and class names available in the current project can be auto-completed.
spring-bean-reference	Auto-complete the available bean names in the current project. Usually constrained by a base class that is specified via the target parameter.
spring-profile-name	Auto-complete the available Spring profile names in the project.

Тір

No more than one provider can be active for a given property but you can specify several providers if they can all manage the property *in some ways*. Make sure to place the most powerful provider first as the IDE must use the first one in the JSON section it can handle. If no provider for a given property is supported, no special content assistance is provided either.

Any

The **any** provider permits any additional values to be provided. Regular value validation based on the property type should be applied if this is supported.

This provider will be typically used if you have a list of values and any extra values are still to be considered as valid.

The example below offers on and off as auto-completion values for system.state; any other value is also allowed:

Class reference

The **class-reference** provider auto-completes classes available in the project. This provider supports these parameters:

Parameter	Туре	Default value	Description
target	String (Class)	none	The fully qualified name of the class that should be assignable to the chosen value. Typically used to filter out non candidate classes. Note that this information can be provided by the type itself by exposing a class with the appropriate upper bound.
concrete	boolean	true	Specify if only concrete classes are to be considered as valid candidates.

The meta-data snippet below corresponds to the standard server.jsp-servlet.class-name property that defines the JspServlet class name to use:

Handle As

The **handle-as** provider allows you to substitute the type of the property to a more high-level type. This typically happens when the property has a java.lang.String type because you don't want your configuration classes to rely on classes that may not be on the classpath. This provider supports these parameters:

Parameter	Туре	Default value	Description
target	String (Class)	none	The fully qualified name of the type to consider for the property. This parameter is mandatory.

The following types can be used:

- Any java.lang.Enum that lists the possible values for the property (By all means, try to define the property with the Enum type instead as no further hint should be required for the IDE to auto-complete the values).
- java.nio.charset.Charset: auto-completion of charset/encoding values (e.g. UTF-8)
- java.util.Locale: auto-completion of locales (e.g. en_US)
- org.springframework.util.MimeType: auto-completion of content type values (e.g. text/ plain)
- org.springframework.core.io.Resource: auto-completion of Spring's Resource abstraction to refer to a file on the filesystem or on the classpath. (e.g. classpath:/foo.properties)

Note

If multiple values can be provided, use a Collection or Array type to teach the IDE about it.

The meta-data snippet below corresponds to the standard liquibase.change-log property that defines the path to the changelog to use. It is actually used internally as a org.springframework.core.io.Resource but cannot be exposed as such as we need to keep the original String value to pass it to the Liquibase API.

Logger name

The **logger-name** provider auto-completes valid logger names. Typically, package and class names available in the current project can be auto-completed. Specific frameworks may have extra magic logger names that could be supported as well.

Since a logger name can be any arbitrary name, really, this provider should allow any value but could highlight valid packages and class names that are not available in the project's classpath.

The meta-data snippet below corresponds to the standard logging.level property, keys are *logger names* and values correspond to the standard log levels or any custom level:

```
{"hints": [
   {
        "name": "logging.level.keys",
        "values": [
           {
                "value": "root",
                "description": "Root logger used to assign the default logging level."
            }
        1,
        "providers": [
            {
                "name": "logger-name"
            }
        1
   },
   {
        "name": "logging.level.values",
        "values": [
            {
                "value": "trace"
            },
            {
                "value": "debug"
            },
            {
                "value": "info"
            },
            {
                "value": "warn"
            },
```

```
{
                 "value": "error"
             },
             {
                 "value": "fatal"
             },
             {
                 "value": "off"
             }
        ],
         "providers": [
             {
                 "name": "any"
             }
        1
    }
1}
```

Spring bean reference

The **spring-bean-reference** provider auto-completes the beans that are defined in the configuration of the current project. This provider supports these parameters:

Pa	arameter	Туре	Default value	Description
ta	arget	String (Class)	none	The fully qualified name of the bean class that should be assignable to the candidate. Typically used to filter out non candidate beans.

The meta-data snippet below corresponds to the standard spring.jmx.server property that defines the name of the MBeanServer bean to use:

Note

The binder is not aware of the meta-data so if you provide that hint, you will still need to transform the bean name into an actual Bean reference using the ApplicationContext.

Spring profile name

The **spring-profile-name** provider auto-completes the Spring profiles that are defined in the configuration of the current project.

The meta-data snippet below corresponds to the standard spring.profiles.active property that defines the name of the Spring profile(s) to enable:

```
{"hints": [
{
```

```
"name": "spring.profiles.active",
    "providers": [
        {
            {"name": "spring-profile-name"
        }
      ]
    }
]
```

B.3 Generating your own meta-data using the annotation processor

You can easily generate your own configuration meta-data file from items annotated with @ConfigurationProperties by using the spring-boot-configuration-processor jar. The jar includes a Java annotation processor which is invoked as your project is compiled. To use the processor, simply include spring-boot-configuration-processor as an optional dependency, for example with Maven you would add:

```
<dependency>
    <groupId>org.springframework.boot</groupId>
    <artifactId>spring-boot-configuration-processor</artifactId>
    <optional>true</optional>
</dependency>
```

With Gradle, you can use the propdeps-plugin and specify:

```
dependencies {
    optional "org.springframework.boot:spring-boot-configuration-processor"
}
compileJava.dependsOn(processResources)
}
```

Note

You need to add compileJava.dependsOn(processResources) to your build to ensure that resources are processed before code is compiled. Without this directive any additional-spring-configuration-metadata.json files will not be processed.

The processor will pick up both classes and methods that are annotated with @ConfigurationProperties. The Javadoc for field values within configuration classes will be used to populate the description attribute.

Note

You should only use simple text with @ConfigurationProperties field Javadoc since they are not processed before being added to the JSON.

Properties are discovered via the presence of standard getters and setters with special handling for collection types (that will be detected even if only a getter is present). The annotation processor also supports the use of the <code>@Data</code>, <code>@Getter</code> and <code>@Setter</code> lombok annotations.

Note

If you are using AspectJ in your project, you need to make sure that the annotation processor only runs once. There are several ways to do this: with Maven, you can configure the maven-apt-

plugin explicitly and add the dependency to the annotation processor only there. You could also let the AspectJ plugin runs all the processing and disable annotation processing in the maven-compiler-plugin configuration:

```
<plugin>
<groupId>org.apache.maven.plugins</groupId>
<artifactId>maven-compiler-plugin</artifactId>
<configuration>
</proc>none</proc>
</configuration>
</plugin>
```

Nested properties

The annotation processor will automatically consider inner classes as nested properties. For example, the following class:

```
@ConfigurationProperties(prefix="server")
public class ServerProperties {
    private String name;
    private Host host;
    // ... getter and setters
    private static class Host {
        private String ip;
        private int port;
        // ... getter and setters
    }
}
```

Will produce meta-data information for server.name, server.host.ip and server.host.port properties. You can use the @NestedConfigurationProperty annotation on a field to indicate that a regular (non-inner) class should be treated as if it were nested.

Adding additional meta-data

Spring Boot's configuration file handling is quite flexible; and it is often the case that properties may exist that are not bound to a @ConfigurationProperties bean. You may also need to tune some attributes of an existing key. To support such cases and allow you to provide custom "hints", the annotation processor will automatically merge items from META-INF/additional-spring-configuration-metadata.json into the main meta-data file.

If you refer to a property that has been detected automatically, the description, default value and deprecation information are overridden if specified. If the manual property declaration is not identified in the current module, it is added as a brand new property.

The format of the additional-spring-configuration-metadata.json file is exactly the same as the regular spring-configuration-metadata.json. The additional properties file is optional, if you don't have any additional properties, simply don't add it.

Appendix C. Auto-configuration classes

Here is a list of all auto-configuration classes provided by Spring Boot with links to documentation and source code. Remember to also look at the autoconfig report in your application for more details of which features are switched on. (start the app with --debug or -Ddebug, or in an Actuator application use the autoconfig endpoint).

C.1 From the "spring-boot-autoconfigure" module

The following auto-configuration classes are from the spring-boot-autoconfigure module:

Configuration Class	Links
ActiveMQAutoConfiguration	javadoc
AopAutoConfiguration	javadoc

<u>TraceWebFilterAutoConfiguration</u>	<u>javadoc</u>

Appendix D. The executable jar format

The spring-boot-loader modules allows Spring Boot to support executable jar and war files. If you're using the Maven or Gradle plugin, executable jars are automatically generated and you generally won't need to know the details of how they work.

If you need to create executable jars from a different build system, or if you are just curious about the underlying technology, this section provides some background.

D.1 Nested JARs

Java does not provide any standard way to load nested jar files (i.e. jar files that are themselves contained within a jar). This can be problematic if you are looking to distribute a self-contained application that you can just run from the command line without unpacking.

To solve this problem, many developers use "shaded" jars. A shaded jar simply packages all classes, from all jars, into a single 'uber jar'. The problem with shaded jars is that it becomes hard to see which libraries you are actually using in your application. It can also be problematic if the same filename is used (but with different content) in multiple jars. Spring Boot takes a different approach and allows you to actually nest jars directly.

The executable jar file structure

Spring Boot Loader compatible jar files should be structured in the following way:

```
example.jar
+-META-INF
+-MANIFEST.MF
+-org
   +-springframework
      +-boot
        +-loader
            +-<spring boot loader classes>
 +-com
   +-mycompany
      + project
         +-YouClasses.class
 +-lib
   +-dependency1.jar
   +-dependency2.jar
```

Dependencies should be placed in a nested lib directory.

The executable war file structure

Spring Boot Loader compatible war files should be structured in the following way:

```
example.war

+-META-INF

+-MANIFEST.MF

+-org

+-springframework

+-boot
```

```
| +-loader
| +-<spring boot loader classes>
+-WEB-INF
+-classes
| +-com
| +-mycompany
| +-project
| +-YouClasses.class
+-lib
| +-dependency1.jar
| +-dependency2.jar
+-lib-provided
+-servlet-api.jar
+-dependency3.jar
```

Dependencies should be placed in a nested WEB-INF/lib directory. Any dependencies that are required when running embedded but are not required when deploying to a traditional web container should be placed in WEB-INF/lib-provided.

D.2 Spring Boot's "JarFile" class

The core class used to support loading nested jars is org.springframework.boot.loader.jar.JarFile. It allows you load jar content from a standard jar file, or from nested child jar data. When first loaded, the location of each JarEntry is mapped to a physical file offset of the outer jar:

myapp.jar	+	+
 A.class 	B.class	b.jar ++ B.class ++
+	+	+
^	^	^
0063	3452	3980

The example above shows how A.class can be found in myapp.jar position 0063. B.class from the nested jar can actually be found in myapp.jar position 3452 and B.class is at position 3980.

Armed with this information, we can load specific nested entries by simply seeking to appropriate part if the outer jar. We don't need to unpack the archive and we don't need to read all entry data into memory.

Compatibility with the standard Java "JarFile"

Spring Boot Loader strives to remain compatible with existing code and libraries. org.springframework.boot.loader.jar.JarFile extends from java.util.jar.JarFile and should work as a drop-in replacement. The getURL() method will return a URL that opens a java.net.JarURLConnection compatible connection and can be used with Java's URLClassLoader.

D.3 Launching executable jars

The org.springframework.boot.loader.Launcher class is a special bootstrap class that is used as an executable jars main entry point. It is the actual Main-Class in your jar file and it's used to setup an appropriate URLClassLoader and ultimately call your main() method.

There are 3 launcher subclasses (JarLauncher, WarLauncher and PropertiesLauncher). Their purpose is to load resources (.class files etc.) from nested jar files or war files in directories (as

opposed to explicitly on the classpath). In the case of the [Jar|War]Launcher the nested paths are fixed (lib/*.jar and lib-provided/*.jar for the war case) so you just add extra jars in those locations if you want more. The PropertiesLauncher looks in lib/ in your application archive by default, but you can add additional locations by setting an environment variable LOADER_PATH or loader.path in application.properties (comma-separated list of directories or archives).

Launcher manifest

You need to specify an appropriate Launcher as the Main-Class attribute of META-INF/ MANIFEST.MF. The actual class that you want to launch (i.e. the class that you wrote that contains a main method) should be specified in the Start-Class attribute.

For example, here is a typical MANIFEST.MF for an executable jar file:

```
Main-Class: org.springframework.boot.loader.JarLauncher
Start-Class: com.mycompany.project.MyApplication
```

For a war file, it would be:

```
Main-Class: org.springframework.boot.loader.WarLauncher
Start-Class: com.mycompany.project.MyApplication
```

Note

You do not need to specify Class-Path entries in your manifest file, the classpath will be deduced from the nested jars.

Exploded archives

Certain PaaS implementations may choose to unpack archives before they run. For example, Cloud Foundry operates in this way. You can run an unpacked archive by simply starting the appropriate launcher:

```
$ unzip -q myapp.jar
$ java org.springframework.boot.loader.JarLauncher
```

D.4 PropertiesLauncher Features

PropertiesLauncher has a few special features that can be enabled with external properties (System properties, environment variables, manifest entries or application.properties).

Кеу	Purpose
loader.path	Comma-separated Classpath, e.g. lib, \${HOME}/app/lib. Earlier entries take precedence, just like a regular -classpath on the javac command line.
loader.home	Location of additional properties file, e.g. $/opt/app$ (defaults to $\{user.dir\}$)
loader.args	Default arguments for the main method (space separated)
loader.main	Name of main class to launch, e.g. com.app.Application.

Кеу	Purpose
loader.config.name	Name of properties file, e.g. loader (defaults to application).
loader.config.location	Path to properties file, e.g. classpath:loader.properties (defaults to application.properties).
loader.system	Boolean flag to indicate that all properties should be added to System properties (defaults to $false$)

Manifest entry keys are formed by capitalizing initial letters of words and changing the separator to "-" from "." (e.g. Loader-Path). The exception is loader.main which is looked up as Start-Class in the manifest for compatibility with JarLauncher).

Тір

Build plugins automatically move the Main-Class attribute to Start-Class when the fat jar is built. If you are using that, specify the name of the class to launch using the Main-Class attribute and leave out Start-Class.

Environment variables can be capitalized with underscore separators instead of periods.

- loader.home is the directory location of an additional properties file (overriding the default) as long as loader.config.location is not specified.
- loader.path can contain directories (scanned recursively for jar and zip files), archive paths, or wildcard patterns (for the default JVM behavior).
- loader.path (if empty) defaults to lib (meaning a local directory or a nested one if running from an archive). Because of this PropertiesLauncher behaves the same as JarLauncher when no additional configuration is provided.
- Placeholder replacement is done from System and environment variables plus the properties file itself on all values before use.

D.5 Executable jar restrictions

There are a number of restrictions that you need to consider when working with a Spring Boot Loader packaged application.

Zip entry compression

The *ZipEntry* for a nested jar must be saved using the *ZipEntry*.STORED method. This is required so that we can seek directly to individual content within the nested jar. The content of the nested jar file itself can still be compressed, as can any other entries in the outer jar.

System ClassLoader

Launched applications should use Thread.getContextClassLoader() when loading classes (most libraries and frameworks will do this by default). Trying to load nested jar classes via ClassLoader.getSystemClassLoader() will fail. Please be aware that java.util.Logging always uses the system classloader, for this reason you should consider a different logging implementation.

D.6 Alternative single jar solutions

If the above restrictions mean that you cannot use Spring Boot Loader the following alternatives could be considered:

- Maven Shade Plugin
- JarClassLoader
- OneJar

Appendix E. Dependency versions

The table below provides details of all of the dependency versions that are provided by Spring Boot in its CLI, Maven dependency management and Gradle plugin. When you declare a dependency on one of these artifacts without declaring a version the version that is listed in the table will be used.

Group ID	Artifact ID	Version
antlr	antlr	2.7.7
ch.qos.logback	logback-access	1.1.5
