Table of Contents

1. Preface

The Spring AMQP project applies core Spring concepts to the development of AMQP-based messaging solutions. We provide a "template" as a high-level abstraction for sending and receiving messages. We also provide support for Message-driven POJOs. These libraries facilitate management of AMQP resources while promoting the use of dependency injection and declarative configuration. In all of these cases, you will see similarities to the JMS support in the Spring Framework. For other project-related information visit the Spring AMQP project homepage.

2. Introduction

This first part of the reference documentation is a high-level overview of Spring AMQP and the underlying concepts and some code snippets that will get you up and running as quickly as possible.

2.1 Quick Tour for the impatient

Introduction

This is the 5 minute tour to get started with Spring AMQP.

Prerequisites: install and run the RabbitMQ broker (http://www.rabbitmq.com/download.html). Then grab the spring-rabbit JAR and all its dependencies - the easiest way to do that is to declare a dependency in your build tool, e.g. for Maven:

```
<dependency>
  <groupId>org.springframework.amqp</groupId>
  <artifactId>spring-rabbit</artifactId>
  <version>1.5.4.RELEASE</version>
</dependency>
```

And for gradle:

```
compile 'org.springframework.amqp:spring-rabbit:1.5.4.RELEASE'
```

Compatibility

While the default Spring Framework version dependency is 4.2.x, Spring AMQP is generally compatible with earlier versions of Spring Framework. Annotation-based listeners and the `RabbitMessagingTemplate` require Spring Framework 4.1 or higher, however.

Similarly, the default `amqp-client` version is 3.5.x but the framework is generally compatible with earlier versions. However, of course, features that rely on newer client versions will not be available.

Very, Very Quick

Using plain, imperative Java to send and receive a message:

```
ConnectionFactory connectionFactory = new CachingConnectionFactory();

AmqpAdmin admin = new RabbitAdmin(connectionFactory);
admin.declareQueue(new Queue("myqueue"));

AmqpTemplate template = new RabbitTemplate(connectionFactory);
template.convertAndSend("myqueue", "foo");

String foo = (String) template.receiveAndConvert("myqueue");
```

Note that there is a `ConnectionFactory` in the native Java Rabbit client as well. We are using the Spring abstraction in the code above. We are relying on the default exchange in the broker (since none is specified in the send), and the default binding of all queues to the default exchange by their name (hence we can use the queue name as a routing key in the send). Those behaviours are defined in the AMQP specification.

With XML Configuration

The same example as above, but externalizing the resource configuration to XML:

```
ApplicationContext context =
    new GenericXmlApplicationContext("classpath:/rabbit-context.xml");
AmqpTemplate template = context.getBean(AmqpTemplate.class);

template.convertAndSend("myqueue", "foo");

String foo = (String) template.receiveAndConvert("myqueue");
```

```
<beans xmlns="http://www.springframework.org/schema/beans"
       xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
       xmlns:rabbit="http://www.springframework.org/schema/rabbit"
       xsi:schemaLocation="http://www.springframework.org/schema/rabbit
           http://www.springframework.org/schema/rabbit/spring-rabbit.xsd
           http://www.springframework.org/schema/beans
           http://www.springframework.org/schema/beans/spring-beans.xsd">

    <rabbit:connection-factory id="connectionFactory"/>

    <rabbit:template id="amqpTemplate" connection-factory="connectionFactory"/>

    <rabbit:admin connection-factory="connectionFactory"/>

    <rabbit:queue name="myqueue"/>

</beans>
```

The `<rabbit:admin/>` declaration by default automatically looks for beans of type `Queue`, `Exchange` and `Binding` and declares them to the broker on behalf of the user, hence there is no need to use that bean explicitly in the simple Java driver. There are plenty of options to configure the properties of the components in the XML schema - you can use auto-complete features of your XML editor to explore them and look at their documentation.

With Java Configuration

The same example again with the external configuration in Java:

```
ApplicationContext context =
    new AnnotationConfigApplicationContext(RabbitConfiguration.class);
AmqpTemplate template = context.getBean(AmqpTemplate.class);

template.convertAndSend("myqueue", "foo");

String foo = (String) template.receiveAndConvert("myqueue");
```

```
@Configuration
public class RabbitConfiguration {

    @Bean
    public ConnectionFactory connectionFactory() {
        CachingConnectionFactory connectionFactory =
            new CachingConnectionFactory("localhost");
        return connectionFactory;
    }

    @Bean
    public AmqpAdmin amqpAdmin() {
        return new RabbitAdmin(connectionFactory());
    }

    @Bean
    public RabbitTemplate rabbitTemplate() {
        return new RabbitTemplate(connectionFactory());
    }

    @Bean
    public Queue myQueue() {
       return new Queue("myqueue");
    }
}
```

2.2 What's New

Changes in 1.5 Since 1.4

spring-erlang is No Longer Supported

The `spring-erlang` jar is no longer included in the distribution. Use the section called "RabbitMQ REST API" instead.

CachingConnectionFactory Changes

Empty Addresses Property in CachingConnectionFactory

Previously, if the connection factory was configured with a host/port, but an empty String was also supplied for `addresses`, the host and port were ignored. Now, an empty `addresses` String is treated the same as a `null`, and the host/port will be used.

URI Constructor

The `CachingConnectionFactory` has an additional constructor, with a `URI` parameter, to configure the broker connection.

Connection Reset

A new method `resetConnection()` has been added to allow users to reset the connection (or connections). This might be used, for example, to reconnect to the primary broker after failing over to the secondary broker. This **will** impact in-process operations. The existing `destroy()` method does exactly the same, but the new method has a less daunting name.

Properties to Control Container Queue Declaration Behavior

When the listener container consumers start, they attempt to passively declare the queues to ensure they are available on the broker. Previously, if these declarations failed, for example because the queues didn't exist, or when an HA queue was being moved, the retry logic was fixed at 3 retry attempts at 5 second intervals. If the queue(s) still do not exist, the behavior is controlled by the

`missingQueuesFatal` property (default true). Also, for containers configured to listen from multiple queues, if only a subset of queues are available, the consumer retried the missing queues on a fixed interval of 60 seconds.

These 3 properties (`declarationRetries`, `failedDeclarationRetryInterval`, `retryDeclarationInterval`) are now configurable. See the section called “Message Listener Container Configuration” for more information.

Class Package Change

The `RabbitGatewaySupport` class has been moved from `o.s.amqp.rabbit.core.support` to `o.s.amqp.rabbit.core`.

DefaultMessagePropertiesConverter

The `DefaultMessagePropertiesConverter` can now be configured to determine the maximum length of a `LongString` that will be converted to a `String` rather than a `DataInputStream`. The converter has an alternative constructor that takes the value as a limit. Previously, this limit was hard-coded at `1024` bytes. (Also available in *1.4.4*).

@RabbitListener Improvements

@QueueBinding for @RabbitListener

The `bindings` attribute has been added to the `@RabbitListener` annotation as mutually exclusive with the `queues` attribute to allow the specification of the `queue`, its `exchange` and `binding` for declaration by a `RabbitAdmin` on the Broker.

SpEL in @SendTo

The default reply address (`@SendTo`) for a `@RabbitListener` can now be a SpEL expression.

Multiple Queue Names Via Properties

It is now possible to use a combination of SpEL and property placeholders to specify multiple queues for a listener.

See the section called “Annotation-driven Listener Endpoints” for more information.

Automatic Exchange, Queue, Binding Declaration

It is now possible to declare beans that define a collection of these entities and the `RabbitAdmin` will add the contents to the list of entities that it will declare when a connection is established. See the section called “Declaring Collections of Exchanges, Queues, Bindings” for more information.

RabbitTemplate Changes

reply-address

The `reply-address` attribute has been added to the `<rabbit-template>` component as an alternative `reply-queue`. See the section called “Request/Reply Messaging” for more information. (Also available in *1.4.4* as a setter on the `RabbitTemplate`).

Blocking Receive Methods

The `RabbitTemplate` now supports blocking in `receive` and `convertAndReceive` methods. See the section called “Polling Consumer” for more information.

Mandatory with SendAndReceive Methods

When the `mandatory` flag is set when using `sendAndReceive` and `convertSendAndReceive` methods, the calling thread will throw an `AmqpMessageReturnedException` if the request message can't be deliverted. See the section called "Reply Timeout" for more information.

Improper Reply Listener Configuration

The framework will attempt to verify proper configuration of a reply listener container when using a named reply queue.

See the section called "Reply Listener Container" for more information.

The RabbitManagementTemplate

The `RabbitManagementTemplate` has been introduced to monitor and configure the RabbitMQ Broker using the REST API provided by its Management Plugin. See the section called "RabbitMQ REST API" for more information.

Listener Container Bean Names (XML)

> **Important**
>
> The `id` attribute on the `<listener-container/>` element has been removed. Starting with this release, the `id` on the `<listener/>` child element is used alone to name the listener container bean created for each listener element.
>
> Normal Spring bean name overrides are applied; if a later `<listener/>` is parsed with the same `id` as an existing bean, the new definition will override the existing one. Previously, bean names were composed from the ids of the `<listener-container/>` and `<listener/>` elements.
>
> When migrating to this release, if you have `id` s on your `<listener-container/>` elements, remove them and set the `id` on the child `<listener/>` element instead.

However, to support starting/stopping containers as a group, a new `group` attribute has been added. When this attribute is defined, the containers created by this element are added to a bean with this name, of type `Collection<SimpleMessageListenerContainer`. You can iterate over this group to start/stop containers.

Class-Level @RabbitListener

The `@RabbitListener` annotation can now be applied at the class level. Together with the new `@RabbitHandler` method annotation, this allows the handler method to be selected based on payload type. See the section called "Multi-Method Listeners" for more information.

SimpleMessageListenerContainer: BackOff support

The `SimpleMessageListenerContainer` can now be supplied with a `BackOff` instance for `consumer` startup recovery. See the section called "Message Listener Container Configuration" for more information.

Channel Close Logging

A mechanism to control the log levels of channel closure has been introduced. See the section called "Logging Channel Close Events".

Application Events

The `SimpleMessageListenerContainer` now emits application events when consumers fail. See the section called “Consumer Failure Events” for more information.

Consumer Tag Configuration

Previously, the consumer tags for asynchronous consumers were generated by the broker. With this release, it is now possible to supply a naming strategy to the listener container. See the section called “Consumer Tags”.

MessageListenerAdapter

The `MessageListenerAdapter` now supports a map of queue names (or consumer tags) to method names, to determine which delegate method to call based on the queue the message was received from.

LocalizedQueueConnectionFactory

A new connection factory that connects to the node in a cluster where a mirrored queue actually resides.

See the section called “Queue Affinity and the LocalizedQueueConnectionFactory”.

Anonymous Queue Naming

Starting with *version 1.5.3*, you can now control how `AnonymousQueue` names are generated. See the section called “AnonymousQueue” for more information.

Changes in 1.4 Since 1.3

@RabbitListener Annotation

POJO listeners can be annotated with `@RabbitListener`, enabled by `@EnableRabbit` or `<rabbit:annotation-driven />`. Spring Framework 4.1 is required for this feature. See the section called “Annotation-driven Listener Endpoints” for more information.

RabbitMessagingTemplate

A new `RabbitMessagingTemplate` is provided to allow users to interact with RabbitMQ using `spring-messaging Message`s. It uses the `RabbitTemplate` internally which can be configured as normal. Spring Framework 4.1 is required for this feature. See the section called “Messaging integration” for more information.

Listener Container *Missing Queues Fatal* Attribute

1.3.5 introduced the `missingQueuesFatal` property on the `SimpleMessageListenerContainer`. This is now available on the listener container namespace element. See the section called “Message Listener Container Configuration”.

RabbitTemplate *ConfirmCallback* Interface

The `confirm` method on this interface has an additional parameter `cause`. When available, this parameter will contain the reason for a negative acknowledgement (nack). See the section called “Publisher Confirms and Returns”.

RabbitConnectionFactoryBean

A factory bean is now provided to create the underlying RabbitMQ `ConnectionFactory` used by the `CachingConnectionFactory`. This enables configuration of SSL options using Spring's dependency injection. See the section called "Configuring the Underlying Client Connection Factory".

CachingConnectionFactory

The `CachingConnectionFactory` now allows the `connectionTimeout` to be set as a property or as an attribute in the namespace. It sets the property on the underlying RabbitMQ `ConnectionFactory` See the section called "Configuring the Underlying Client Connection Factory".

Log Appender

The Logback `org.springframework.amqp.rabbit.logback.AmqpAppender` has been introduced. It provides similar options like `org.springframework.amqp.rabbit.log4j.AmqpAppender`. For more info see JavaDocs of these classes.

The Log4j `AmqpAppender` now supports the `deliveryMode` property (`PERSISTENT` or `NON_PERSISTENT`, default: `PERSISTENT`). Previously, all log4j messages were PERSISTENT.

The appender also supports modification of the `Message` before sending - allowing, for example, the addition of custom headers. Subclasses should override the `postProcessMessageBeforeSend()`.

Listener Queues

The listener container now, by default, redeclares any missing queues during startup. A new `auto-declare` attribute has been added to the `<rabbit:listener-container>` to prevent these redeclarations. See the section called "*auto-delete* Queues".

RabbitTemplate: mandatory and connectionFactorySelector Expressions

The `mandatoryExpression` and `sendConnectionFactorySelectorExpression` and `receiveConnectionFactorySelectorExpression` SpEL `Expression`s properties have been added to the `RabbitTemplate`. The `mandatoryExpression` is used to evaluate a `mandatory` boolean value against each request message, when a `ReturnCallback` is in use. See the section called "Publisher Confirms and Returns". The `sendConnectionFactorySelectorExpression` and `receiveConnectionFactorySelectorExpression` are used when an `AbstractRoutingConnectionFactory` is provided, to determine the `lookupKey` for the target `ConnectionFactory` at runtime on each AMQP protocol interaction operation. See the section called "Routing Connection Factory".

Listeners and the Routing Connection Factory

A `SimpleMessageListenerContainer` can be configured with a routing connection factory to enable connection selection based on the queue names. See the section called "Routing Connection Factory".

RabbitTemplate: RecoveryCallback option

The `recoveryCallback` property has been added to be used in the `retryTemplate.execute()`. See the section called "Adding Retry Capabilities".

MessageConversionException

This exception is now a subclass of `AmqpException`; if you have code like the following:

```
try {
    template.convertAndSend("foo", "bar", "baz");
}
catch (AmqpException e) {
 ...
}
catch (MessageConversionException e) {
 ...
}
```

The second catch block will no longer be reachable and needs to be moved above the catch-all `AmqpException` catch block.

RabbitMQ 3.4 Compatibility

Spring AMQP is now compatible with the **RabbitMQ 3.4**, including direct reply-to; see the section called “Compatibility” and the section called “RabbitMQ Direct reply-to” for more information.

ContentTypeDelegatingMessageConverter

The `ContentTypeDelegatingMessageConverter` has been introduced to select the `MessageConverter` to use, based on the `contentType` property in the `MessageProperties`. See the section called “Message Converters” for more information.

Changes in 1.3 Since 1.2

Listener Concurrency

The listener container now supports dynamic scaling of the number of consumers based on workload, or the concurrency can be programmatically changed without stopping the container. See the section called “Listener Concurrency”.

Listener Queues

The listener container now permits the queue(s) on which it is listening to be modified at runtime. Also, the container will now start if at least one of its configured queues is available for use. See the section called “Listener Container Queues”

This listener container will now redeclare any auto-delete queues during startup. See the section called “*auto-delete* Queues”.

Consumer Priority

The listener container now supports consumer arguments, allowing the `x-priority` argument to be set. See the section called “Container”.

Exclusive Consumer

The `SimpleMessageListenerContainer` can now be configured with a single `exclusive` consumer, preventing other consumers from listening to the queue. See the section called “Exclusive Consumer”.

Rabbit Admin

It is now possible to have the Broker generate the queue name, regardless of durable, autoDelete and exclusive settings. See the section called “Configuring the broker”.

Direct Exchange Binding

Previously, omitting the `key` attribute from a `binding` element of a `direct-exchange` configuration caused the queue or exchange to be bound with an empty string as the routing key. Now it is bound with the the name of the provided `Queue` or `Exchange`. Users wishing to bind with an empty string routing key need to specify `key=""`.

AMQP Template

The `AmqpTemplate` now provides several synchronous `receiveAndReply` methods. These are implemented by the `RabbitTemplate`. For more information see the section called “Receiving messages”.

The `RabbitTemplate` now supports configuring a `RetryTemplate` to attempt retries (with optional back off policy) for when the broker is not available. For more information see the section called “Adding Retry Capabilities”.

Caching Connection Factory

The caching connection factory can now be configured to cache `Connection`s and their `Channel`s instead of using a single connection and caching just `Channel`s. See the section called “Connection and Resource Management”.

Binding Arguments

The `<exchange>`'s `<binding>` now supports parsing of the `<binding-arguments>` sub-element. The `<headers-exchange>`'s `<binding>` now can be configured with a `key/value` attribute pair (to match on a single header) or with a `<binding-arguments>` sub-element, allowing matching on multiple headers; these options are mutually exclusive. See the section called “Introduction”.

Routing Connection Factory

A new `SimpleRoutingConnectionFactory` has been introduced, to allow configuration of `ConnectionFactories` mapping to determine the target `ConnectionFactory` to use at runtime. See the section called “Routing Connection Factory”.

MessageBuilder and MessagePropertiesBuilder

"Fluent APIs" for building messages and/or message properties is now provided. See the section called “Message Builder API”.

RetryInterceptorBuilder

A "Fluent API" for building listener container retry interceptors is now provided. See the section called “Failures in Synchronous Operations and Options for Retry”.

RepublishMessageRecoverer

This new `MessageRecoverer` is provided to allow publishing a failed message to another queue (including stack trace information in the header) when retries are exhausted. See the section called “Message Listeners and the Asynchronous Case”.

Default Error Handler (Since 1.3.2)

A default `ConditionalRejectingErrorHandler` has been added to the listener container. This error handler detects message conversion problems (which are fatal) and instructs the container to reject the message to prevent the broker from continually redelivering the unconvertible message. See the section called “Exception Handling”.

Listener Container 'missingQueuesFatal` Property (Since 1.3.5)

The `SimpleMessageListenerContainer` now has a property `missingQueuesFatal` (default `true`). Previously, missing queues were always fatal. See the section called “Message Listener Container Configuration”.

Changes to 1.2 Since 1.1

RabbitMQ Version

Spring AMQP now using RabbitMQ 3.1.x by default (but retains compatibility with earlier versions). Certain deprecations have been added for features no longer supported by RabbitMQ 3.1.x - federated exchanges and the `immediate` property on the `RabbitTemplate`.

Rabbit Admin

The `RabbitAdmin` now provides an option to allow exchange, queue, and binding declarations to continue when a declaration fails. Previously, all declarations stopped on a failure. By setting `ignore-declaration-exceptions`, such exceptions are logged (WARN), but further declarations continue. An example where this might be useful is when a queue declaration fails because of a slightly different `ttl` setting would normally stop other declarations from proceeding.

The `RabbitAdmin` now provides an additional method `getQueueProperties()`. This can be used to determine if a queue exists on the broker (returns null for a non-existent queue). In addition, the current number of messages in the queue, as well as the current number of consumers is returned.

Rabbit Template

Previously, when using the `...sendAndReceive()` methods were used with a fixed reply queue, two custom headers were used for correlation data and to retain/restore reply queue information. With this release, the standard message property `correlationId` is used by default, although the user can specifiy a custom property to use instead. In addition, nested `replyTo` information is now retained internally in the template, instead of using a custom header.

The `immediate` property is deprecated; users must not set this property when using RabbitMQ 3.0.x or greater.

JSON Message Converters

A Jackson 2.x `MessageConverter` is now provided, along with the existing converter that uses Jackson 1.x.

Automatic Declaration of Queues, etc

Previously, when declaring queues, exchanges and bindings, it was not possible to define which connection factory was used for the declarations, each `RabbitAdmin` would declare all components using its connection.

Starting with this release, it is now possible to limit declarations to specific `RabbitAdmin` instances. See the section called “Conditional Declaration”.

AMQP Remoting

Facilities are now provided for using Spring Remoting techniques, using AMQP as the transport for the RPC calls. For more information see the section called “Spring Remoting with AMQP”

Requested Heart Beats

Several users have asked for the underlying client connection factory's `requestedHeartBeats` property to be exposed on the Spring AMQP `CachingConnectionFactory`. This is now available; previously, it was necessary to configure the AMQP client factory as a separate bean and provide a reference to it in the `CachingConnectionFactory`.

Changes to 1.1 Since 1.0

General

Spring-AMQP is now built using gradle.

Adds support for publisher confirms and returns.

Adds support for HA queues, and broker failover.

Adds support for Dead Letter Exchanges/Dead Letter Queues.

AMQP Log4j Appender

Adds an option to support adding a message id to logged messages.

Adds an option to allow the specification of a `Charset` name to be used when converting `String`s to `byte[]`.

3. Reference

This part of the reference documentation details the various components that comprise Spring AMQP. The main chapter covers the core classes to develop an AMQP application. This part also includes a chapter about the sample applications.

3.1 Using Spring AMQP

In this chapter, we will explore the interfaces and classes that are the essential components for developing applications with Spring AMQP.

AMQP Abstractions

Introduction

Spring AMQP consists of a handful of modules, each represented by a JAR in the distribution. These modules are: spring-amqp, and spring-rabbit. The *spring-amqp* module contains the `org.springframework.amqp.core` package. Within that package, you will find the classes that represent the core AMQP "model". Our intention is to provide generic abstractions that do not rely on any particular AMQP broker implementation or client library. End user code will be more portable across vendor implementations as it can be developed against the abstraction layer only. These abstractions are then used implemented by broker-specific modules, such as *spring-rabbit*. There is currently only a RabbitMQ implementation; however the abstractions have been validated in .NET using Apache Qpid in addition to RabbitMQ. Since AMQP operates at the protocol level in principle, the RabbitMQ client can be used with any broker that supports the same protocol version, but we do not test any other brokers at present.

The overview here assumes that you are already familiar with the basics of the AMQP specification. If you are not, then have a look at the resources listed in Chapter 5, *Other Resources*

Message

The 0-8 and 0-9-1 AMQP specifications do not define a Message class or interface. Instead, when performing an operation such as `basicPublish()`, the content is passed as a byte-array argument and additional properties are passed in as separate arguments. Spring AMQP defines a Message class as part of a more general AMQP domain model representation. The purpose of the Message class is to simply encapsulate the body and properties within a single instance so that the API can in turn be simpler. The Message class definition is quite straightforward.

```
public class Message {

    private final MessageProperties messageProperties;

    private final byte[] body;

    public Message(byte[] body, MessageProperties messageProperties) {
        this.body = body;
        this.messageProperties = messageProperties;
    }

    public byte[] getBody() {
        return this.body;
    }

    public MessageProperties getMessageProperties() {
        return this.messageProperties;
    }
}
```

The `MessageProperties` interface defines several common properties such as *messageId*, *timestamp*, *contentType*, and several more. Those properties can also be extended with user-defined *headers* by calling the `setHeader(String key, Object value)` method.

Exchange

The `Exchange` interface represents an AMQP Exchange, which is what a Message Producer sends to. Each Exchange within a virtual host of a broker will have a unique name as well as a few other properties:

```
public interface Exchange {

    String getName();

    String getExchangeType();

    boolean isDurable();

    boolean isAutoDelete();

    Map<String, Object> getArguments();

}
```

As you can see, an Exchange also has a *type* represented by constants defined in `ExchangeTypes`. The basic types are: `Direct`, `Topic`, `Fanout`, and `Headers`. In the core package you will find implementations of the `Exchange` interface for each of those types. The behavior varies across these Exchange types in terms of how they handle bindings to Queues. For example, a Direct exchange allows for a Queue to be bound by a fixed routing key (often the Queue's name). A Topic exchange supports bindings with routing patterns that may include the * and # wildcards for *exactly-one* and *zero-or-more*, respectively. The Fanout exchange publishes to all Queues that are bound to it without taking any routing key into consideration. For much more information about these and the other Exchange types, check out Chapter 5, *Other Resources*.

> **Note**
>
> The AMQP specification also requires that any broker provide a "default" Direct Exchange that has no name. All Queues that are declared will be bound to that default Exchange with their names as routing keys. You will learn more about the default Exchange's usage within Spring AMQP in the section called "AmqpTemplate".

Queue

The `Queue` class represents the component from which a Message Consumer receives Messages. Like the various Exchange classes, our implementation is intended to be an abstract representation of this core AMQP type.

```
public class Queue  {

    private final String name;

    private volatile boolean durable;

    private volatile boolean exclusive;

    private volatile boolean autoDelete;

    private volatile Map<String, Object> arguments;

    /**
     * The queue is durable, non-exclusive and non auto-delete.
     *
     * @param name the name of the queue.
     */
    public Queue(String name) {
        this(name, true, false, false);
    }

    // Getters and Setters omitted for brevity
```

Notice that the constructor takes the Queue name. Depending on the implementation, the admin template may provide methods for generating a uniquely named Queue. Such Queues can be useful as a "reply-to" address or other **temporary** situations. For that reason, the *exclusive* and *autoDelete* properties of an auto-generated Queue would both be set to *true*.

> **Note**
>
> See the section on queues in the section called “Configuring the broker” for information about declaring queues using namespace support, including queue arguments.

Binding

Given that a producer sends to an Exchange and a consumer receives from a Queue, the bindings that connect Queues to Exchanges are critical for connecting those producers and consumers via messaging. In Spring AMQP, we define a `Binding` class to represent those connections. Let’s review the basic options for binding Queues to Exchanges.

You can bind a Queue to a DirectExchange with a fixed routing key.

```
new Binding(someQueue, someDirectExchange, "foo.bar")
```

You can bind a Queue to a TopicExchange with a routing pattern.

```
new Binding(someQueue, someTopicExchange, "foo.*")
```

You can bind a Queue to a FanoutExchange with no routing key.

```
new Binding(someQueue, someFanoutExchange)
```

We also provide a `BindingBuilder` to facilitate a "fluent API" style.

```
Binding b = BindingBuilder.bind(someQueue).to(someTopicExchange).with("foo.*");
```

> **Note**
>
> The BindingBuilder class is shown above for clarity, but this style works well when using a static import for the *bind()* method.

By itself, an instance of the Binding class is just holding the data about a connection. In other words, it is not an "active" component. However, as you will see later in the section called “Configuring the broker”, Binding instances can be used by the `AmqpAdmin` class to actually trigger the binding actions on the broker. Also, as you will see in that same section, the Binding instances can be defined using Spring’s `@Bean`-style within `@Configuration` classes. There is also a convenient base class which further simplifies that approach for generating AMQP-related bean definitions and recognizes the Queues, Exchanges, and Bindings so that they will all be declared on the AMQP broker upon application startup.

The `AmqpTemplate` is also defined within the core package. As one of the main components involved in actual AMQP messaging, it is discussed in detail in its own section (see the section called “AmqpTemplate”).

Connection and Resource Management

Introduction

Whereas the AMQP model we described in the previous section is generic and applicable to all implementations, when we get into the management of resources, the details are specific to the broker implementation. Therefore, in this section, we will be focusing on code that exists only within our "spring-rabbit" module since at this point, RabbitMQ is the only supported implementation.

The central component for managing a connection to the RabbitMQ broker is the `ConnectionFactory` interface. The responsibility of a `ConnectionFactory` implementation is to provide an instance of `org.springframework.amqp.rabbit.connection.Connection` which is a wrapper for `com.rabbitmq.client.Connection`. The only concrete implementation we provide is `CachingConnectionFactory` which, by default, establishes a single connection proxy that can be shared by the application. Sharing of the connection is possible since the "unit of work" for messaging with AMQP is actually a "channel" (in some ways, this is similar to the relationship between a Connection and a Session in JMS). As you can imagine, the connection instance provides a `createChannel` method. The `CachingConnectionFactory` implementation supports caching of those channels, and it maintains separate caches for channels based on whether they are transactional or not. When creating an instance of `CachingConnectionFactory`, the *hostname* can be provided via the constructor. The *username* and *password* properties should be provided as well. If you would like to configure the size of the channel cache (the default is 1), you could call the `setChannelCacheSize()` method here as well.

Starting with *version 1.3*, the `CachingConnectionFactory` can be configured to cache connections as well as just channels. In this case, each call to `createConnection()` creates a new connection (or retrieves an idle one from the cache). Closing a connection returns it to the cache (if the cache size has not been reached). Channels created on such connections are cached too. The use of separate connections might be useful in some environments, such as consuming from an HA cluster, in conjunction with a load balancer, to connect to different cluster members.

> **Important**
>
> When the cache mode is `CONNECTION`, automatic declaration of queues etc. (See the section called “Automatic Declaration of Exchanges, Queues and Bindings”) is NOT supported.
>
> Also, at the time of writing, the `rabbitmq-client` library creates a fixed thread pool for each connection (5 threads) by default. When using a large number of connections, you should consider setting a custom `executor` on the `CachingConnectionFactory`. Then, the same executor will be used by all connections and its threads can be shared. The executor’s thread pool should

> be unbounded, or set appropriately for the expected utilization (usually, at least one thread per connection). If multiple channels are created on each connection then the pool size will affect the concurrency, so a variable (or simple cached) thread pool executor would be most suitable.

It is important to understand that the cache size is (by default) not a limit, but merely the number of channels that can be cached. With a cache size of, say, 10, any number of channels can actually be in use. If more than 10 channels are being used and they are all returned to the cache, 10 will go in the cache; the remainder will be physically closed.

Starting with *version 1.4.2*, the `CachingConnectionFactory` has a property `channelCheckoutTimeout`. When this property is greater than zero, the `channelCacheSize` becomes a limit on the number of channels that can be created on a connection. If the limit is reached, calling threads will block until a channel is available or this timeout is reached, in which case a `AmqpTimeoutException` is thrown.

> **Warning**
>
> Channels used within the framework (e.g. `RabbitTemplate`) will be reliably returned to the cache. If you create channels outside of the framework, (e.g. by accessing the connection(s) directly and invoking `createChannel()`), you must return them (by closing) reliably, perhaps in a `finally` block, to avoid running out of channels.

```
CachingConnectionFactory connectionFactory = new CachingConnectionFactory("somehost");
connectionFactory.setUsername("guest");
connectionFactory.setPassword("guest");

Connection connection = connectionFactory.createConnection();
```

When using XML, the configuration might look like this:

```
<bean id="connectionFactory"
      class="org.springframework.amqp.rabbit.connection.CachingConnectionFactory">
    <constructor-arg value="somehost"/>
    <property name="username" value="guest"/>
    <property name="password" value="guest"/>
</bean>
```

> **Note**
>
> There is also a `SingleConnectionFactory` implementation which is only available in the unit test code of the framework. It is simpler than `CachingConnectionFactory` since it does not cache channels, but it is not intended for practical usage outside of simple tests due to its lack of performance and resilience. If you find a need to implement your own `ConnectionFactory` for some reason, the `AbstractConnectionFactory` base class may provide a nice starting point.

A `ConnectionFactory` can be created quickly and conveniently using the rabbit namespace:

```
<rabbit:connection-factory id="connectionFactory"/>
```

In most cases this will be preferable since the framework can choose the best defaults for you. The created instance will be a `CachingConnectionFactory`. Keep in mind that the default cache size for channels is 1. If you want more channels to be cached set a larger value via the *channelCacheSize* property. In XML it would look like this:

```
<bean id="connectionFactory"
      class="org.springframework.amqp.rabbit.connection.CachingConnectionFactory">
    <constructor-arg value="somehost"/>
    <property name="username" value="guest"/>
    <property name="password" value="guest"/>
    <property name="channelCacheSize" value="25"/>
</bean>
```

And with the namespace you can just add the *channel-cache-size* attribute:

```
<rabbit:connection-factory
    id="connectionFactory" channel-cache-size="25"/>
```

The default cache mode is CHANNEL, but you can configure it to cache connections instead; in this case, we use `connection-cache-size`:

```
<rabbit:connection-factory
    id="connectionFactory" cache-mode="CONNECTION" connection-cache-size="25"/>
```

Host and port attributes can be provided using the namespace

```
<rabbit:connection-factory
    id="connectionFactory" host="somehost" port="5672"/>
```

Alternatively, if running in a clustered environment, use the addresses attribute.

```
<rabbit:connection-factory
    id="connectionFactory" addresses="host1:5672,host2:5672"/>
```

Configuring the Underlying Client Connection Factory

The `CachingConnectionFactory` uses an instance of the Rabbit client `ConnectionFactory`; a number of configuration properties are passed through (`host, port, userName, password, requestedHeartBeat, connectionTimeout` for example) when setting the equivalent property on the `CachingConnectionFactory`. To set other properties (`clientProperties` for example), define an instance of the rabbit factory and provide a reference to it using the appropriate constructor of the `CachingConnectionFactory`. When using the namespace as described above, provide a reference to the configured factory in the `connection-factory` attribute. For convenience, a factory bean is provided to assist in configuring the connection factory in a Spring application context, as discussed in the next section.

```
<rabbit:connection-factory
      id="connectionFactory" connection-factory="rabbitConnectionFactory"/>
```

Configuring SSL

Starting with *version 1.4*, a convenient `RabbitConnectionFactoryBean` is provided to enable convenient configuration of SSL properties on the underlying client connection factory, using dependency injection. Other setters simply delegate to the underlying factory. Previously you had to configure the SSL options programmatically.

```
<rabbit:connection-factory id="rabbitConnectionFactory"
    connection-factory="clientConnectionFactory"
    host="${host}"
    port="${port}"
    virtual-host="${vhost}"
    username="${username}" password="${password}" />

<bean id="clientConnectionFactory"
       class="org.springframework.xd.dirt.integration.rabbit.RabbitConnectionFactoryBean">
    <property name="useSSL" value="true" />
    <property name="sslPropertiesLocation" value="file:/secrets/rabbitSSL.properties"/>
</bean>
```

Refer to the RabbitMQ Documentation for information about configuring SSL. Omit the `keyStore` and `trustStore` configuration to connect over SSL without certificate validation. Key and trust store configuration can be provided as follows:

The `sslPropertiesLocation` property is a Spring `Resource` pointing to a properties file containing the following keys:

```
keyStore=file:/secret/keycert.p12
trustStore=file:/secret/trustStore
keyStore.passPhrase=secret
trustStore.passPhrase=secret
```

The `keyStore` and `truststore` are Spring `Resources` pointing to the stores. Typically this properties file will be secured by the operating system with the application having read access.

Starting with Spring AMQP *version 1.5*, these properties can be set directly on the factory bean. If both discrete properties and `sslPropertiesLocation` is provided, properties in the latter will override the discrete values.

Routing Connection Factory

Starting with *version 1.3*, the `AbstractRoutingConnectionFactory` has been introduced. This provides a mechanism to configure mappings for several `ConnectionFactories` and determine a target `ConnectionFactory` by some `lookupKey` at runtime. Typically, the implementation checks a thread-bound context. For convenience, Spring AMQP provides the `SimpleRoutingConnectionFactory`, which gets the current thread-bound `lookupKey` from the `SimpleResourceHolder`:

```
<bean id="connectionFactory"
      class="org.springframework.amqp.rabbit.connection.SimpleRoutingConnectionFactory">
 <property name="targetConnectionFactories">
  <map>
   <entry key="#{connectionFactory1.virtualHost}" ref="connectionFactory1"/>
   <entry key="#{connectionFactory2.virtualHost}" ref="connectionFactory2"/>
  </map>
 </property>
</bean>

<rabbit:template id="template" connection-factory="connectionFactory" />
```

```
public class MyService {

 @Autowired
 private RabbitTemplate rabbitTemplate;

 public void service(String vHost, String payload) {
  SimpleResourceHolder.bind(rabbitTemplate.getConnectionFactory(), vHost);
  rabbitTemplate.convertAndSend(payload);
  SimpleResourceHolder.unbind(rabbitTemplate.getConnectionFactory());
 }

}
```

It is important to unbind the resource after use. For more information see the JavaDocs of `AbstractRoutingConnectionFactory`.

Starting with *version 1.4*, the `RabbitTemplate` supports the SpEL `sendConnectionFactorySelectorExpression` and `receiveConnectionFactorySelectorExpression` properties, which are evaluated on each AMQP protocol interaction operation (`send`, `sendAndReceive`, `receive` or `receiveAndReply`), resolving to a `lookupKey` value for the provided `AbstractRoutingConnectionFactory`. Bean references, such as `"@vHostResolver.getVHost(#root)"` can be used in the expression. For `send` operations, the Message to be sent is the root evaluation object; for `receive` operations, the **queueName** is the root evaluation object.

The **routing** algorithm is: If the selector expression is `null`, or is evaluated to `null`, or the provided `ConnectionFactory` isn't an instance of `AbstractRoutingConnectionFactory`, everything works as before, relying on the provided `ConnectionFactory` implementation. The same occurs if the evaluation result isn't `null`, but there is no target `ConnectionFactory` for that `lookupKey` and the `AbstractRoutingConnectionFactory` is configured with `lenientFallback = true`. Of course, in the case of an `AbstractRoutingConnectionFactory` it does fallback to its `routing` implementation based on `determineCurrentLookupKey()`. But, if `lenientFallback = false`, an `IllegalStateException` is thrown.

The Namespace support also provides the `send-connection-factory-selector-expression` and `receive-connection-factory-selector-expression` attributes on the `<rabbit:template>` component.

Also starting with *version 1.4*, you can configure a routing connection factory in a `SimpleMessageListenerContainer`. In that case, the list of queue names is used as the lookup key. For example, if you configure the container with `setQueueNames("foo", "bar")`, the lookup key will be `"[foo,bar]"` (no spaces).

Queue Affinity and the LocalizedQueueConnectionFactory

When using HA queues in a cluster, for the best performance, it can be desirable to connect to the physical broker where the master queue resides. While the `CachingConnectionFactory` can be configured with multiple broker addresses; this is to fail over and the client will attempt to connect in order. The `LocalizedQueueConnectionFactory` uses the REST API provided by the admin plugin to determine which node the queue is mastered. It then creates (or retrieves from a cache) a `CachingConnectionFactory` that will connect to just that node. If the connection fails, the new master node is determined and the consumer connects to it. The `LocalizedQueueConnectionFactory` is configured with a default connection factory, in case the physical location of the queue cannot be determined, in which case it will connect as normal to the cluster.

The `LocalizedQueueConnectionFactory` is a `RoutingConnectionFactory` and the `SimpleMessageListenerContainer` uses the queue names as the lookup key as discussed in the section called “Routing Connection Factory” above.

> **Note**
>
> For this reason (the use of the queue name for the lookup), the `LocalizedQueueConnectionFactory` can only be used if the container is configured to listen to a single queue.

> **Note**
>
> The RabbitMQ management plugin must be enabled on each node.

> **Caution**
>
> This connection factory is intended for long-lived connections, such as those used by the `SimpleMessageListenerContainer`. It is not intended for short connection use, such as with a `RabbitTemplate` because of the overhead of invoking the REST API before making the connection. Also, for publish operations, the queue is unknown, and the message is published to all cluster members anyway, so the logic of looking up the node has little value.

Here is an example configuration, using Spring Boot’s RabbitProperties to configure the factories:

```
@Autowired
private RabbitProperties props;

private final String[] adminUris = { "http://host1:15672", "http://host2:15672" };

private final String[] nodes = { "rabbit@host1", "rabbit@host2" };

@Bean
public ConnectionFactory defaultConnectionFactory() {
    CachingConnectionFactory cf = new CachingConnectionFactory();
    cf.setAddresses(this.props.getAddresses());
    cf.setUsername(this.props.getUsername());
    cf.setPassword(this.props.getPassword());
    cf.setVirtualHost(this.props.getVirtualHost());
    return cf;
}

@Bean
public ConnectionFactory queueAffinityCF(
        @Qualifier("defaultConnectionFactory") ConnectionFactory defaultCF) {
    return new LocalizedQueueConnectionFactory(defaultCF,
            StringUtils.commaDelimitedListToStringArray(this.props.getAddresses()),
            this.adminUris, this.nodes,
            this.props.getVirtualHost(), this.props.getUsername(), this.props.getPassword(),
            false, null);
}
```

Notice that the first three parameters are arrays of `addresses`, `adminUris` and `nodes`. These are positional in that when a container attempts to connect to a queue, it determines on which node the queue is mastered and connects to the address in the same array position.

Publisher Confirms and Returns

Confirmed and returned messages are supported by setting the `CachingConnectionFactory`'s `publisherConfirms` and `publisherReturns` properties to 'true' respectively.

When these options are set, `Channel`s created by the factory are wrapped in an `PublisherCallbackChannel`, which is used to facilitate the callbacks. When such a channel is obtained, the client can register a `PublisherCallbackChannel.Listener` with the `Channel`. The `PublisherCallbackChannel` implementation contains logic to route a confirm/return to the appropriate listener. These features are explained further in the following sections.

> **Tip**
>
> For some more background information, please see the following blog post by the RabbitMQ team titled Introducing Publisher Confirms.

Logging Channel Close Events

A mechanism to enable users to control logging levels was introduced in *version 1.5*.

The `CachingConnectionFactory` uses a default strategy to log channel closures as follows:

- Normal channel closes (200 OK) are not logged.
- If a channel is closed due to a failed passive queue declaration, it is logged at debug level.
- If a channel is closed because the `basic.consume` is refused due to an exclusive consumer condition, it is logged at INFO level.
- All others are logged at ERROR level.

To modify this behavior, inject a custom `ConditionalExceptionLogger` into the `CachingConnectionFactory` in its `closeExceptionLogger` property.

Also see the section called “Consumer Failure Events”.

AmqpTemplate

Introduction

As with many other high-level abstractions provided by the Spring Framework and related projects, Spring AMQP provides a "template" that plays a central role. The interface that defines the main operations is called `AmqpTemplate`. Those operations cover the general behavior for sending and receiving Messages. In other words, they are not unique to any implementation, hence the "AMQP" in the name. On the other hand, there are implementations of that interface that are tied to implementations of the AMQP protocol. Unlike JMS, which is an interface-level API itself, AMQP is a wire-level protocol. The implementations of that protocol provide their own client libraries, so each implementation of the template interface will depend on a particular client library. Currently, there is only a single implementation: `RabbitTemplate`. In the examples that follow, you will often see usage of an "AmqpTemplate", but when you look at the configuration examples, or any code excerpts where the template is instantiated and/or setters are invoked, you will see the implementation type (e.g. "RabbitTemplate").

As mentioned above, the `AmqpTemplate` interface defines all of the basic operations for sending and receiving Messages. We will explore Message sending and reception, respectively, in the two sections that follow.

Adding Retry Capabilities

Starting with *version 1.3* you can now configure the `RabbitTemplate` to use a `RetryTemplate` to help with handling problems with broker connectivity. Refer to the spring-retry project for complete

information; the following is just one example that uses an exponential back off policy and the default `SimpleRetryPolicy` which will make three attempts before throwing the exception to the caller.

Using the XML namespace:

```
<rabbit:template id="template" connection-factory="connectionFactory" retry-template="retryTemplate"/>

<bean id="retryTemplate" class="org.springframework.retry.support.RetryTemplate">
 <property name="backOffPolicy">
  <bean class="org.springframework.retry.backoff.ExponentialBackOffPolicy">
   <property name="initialInterval" value="500" />
   <property name="multiplier" value="10.0" />
   <property name="maxInterval" value="10000" />
  </bean>
 </property>
</bean>
```

Using `@Configuration`:

```
@Bean
public AmqpTemplate rabbitTemplate();
  RabbitTemplate template = new RabbitTemplate(connectionFactory());
  RetryTemplate retryTemplate = new RetryTemplate();
  ExponentialBackOffPolicy backOffPolicy = new ExponentialBackOffPolicy();
  backOffPolicy.setInitialInterval(500);
  backOffPolicy.setMultiplier(10.0);
  backOffPolicy.setMaxInterval(10000);
  retryTemplate.setBackOffPolicy(backOffPolicy);
  template.setRetryTemplate(retryTemplate);
  return template;
}
```

Starting with *version 1.4*, in addition to the `retryTemplate` property, the `recoveryCallback` option is supported on the `RabbitTemplate`. It is used as a second argument for the `RetryTemplate.execute(RetryCallback<T, E> retryCallback, RecoveryCallback<T>recoveryCallback)`.

> **Note**
>
> The `RecoveryCallback` is somewhat limited in that the retry context only contains the `lastThrowable` field. For more sophisticated use cases, you should use an external `RetryTemplate` so that you can convey additional information to the `RecoveryCallback` via the context's attributes:

```
retryTemplate.execute(
    new RetryCallback<Object, Exception>() {

        @Override
        public Object doWithRetry(RetryContext context) throws Exception {
            context.setAttribute("message", message);
            return rabbitTemplate.convertAndSend(exchange, routingKey, message);
        }
    }, new RecoveryCallback<Object>() {

        @Override
        public Object recover(RetryContext context) throws Exception {
            Object message = context.getAttribute("message");
            Throwable t = context.getLastThrowable();
            // Do something with message
            return null;
        }
    });
}
```

In this case, you would **not** inject a `RetryTemplate` into the `RabbitTemplate`.

Publisher Confirms and Returns

The `RabbitTemplate` implementation of `AmqpTemplate` supports Publisher Confirms and Returns.

For returned messages, the template's `mandatory` property must be set to `true`, or the `mandatory-expression` must evaluate to `true` for a particular message. This feature requires a `CachingConnectionFactory` that has its `publisherReturns` property set to true (see the section called "Publisher Confirms and Returns"). Returns are sent to to the client by it registering a `RabbitTemplate.ReturnCallback` by calling `setReturnCallback(ReturnCallback callback)`. The callback must implement this method:

```
void returnedMessage(Message message, int replyCode, String replyText,
          String exchange, String routingKey);
```

Only one `ReturnCallback` is supported by each `RabbitTemplate`. See also the section called "Reply Timeout".

For Publisher Confirms (aka Publisher Acknowledgements), the template requires a `CachingConnectionFactory` that has its `publisherConfirms` property set to true. Confirms are sent to to the client by it registering a `RabbitTemplate.ConfirmCallback` by calling `setConfirmCallback(ConfirmCallback callback)`. The callback must implement this method:

```
void confirm(CorrelationData correlationData, boolean ack, String cause);
```

The `CorrelationData` is an object supplied by the client when sending the original message. The `ack` is true for an `ack` and false for a `nack`. For `nack` s, the cause may contain a reason for the nack, if it is available when the `nack` is generated. An example is when sending a message to a non-existent exchange. In that case the broker closes the channel; the reason for the closure is included in the `cause`. `cause` was added in *version 1.4*.

Only one `ConfirmCallback` is supported by a `RabbitTemplate`.

> **Note**
>
> When a rabbit template send operation completes, the channel is closed; this would preclude the reception of confirms or returns in the case when the connection factory cache is full (when there is space in the cache, the channel is not physically closed and the returns/confirms will proceed as normal). When the cache is full, the framework defers the close for up to 5 seconds, in order to allow time for the confirms/returns to be received. When using confirms, the channel will be closed when the last confirm is received. When using only returns, the channel will remain open for the full 5 seconds. It is generally recommended to set the connection factory's `channelCacheSize` to a large enough value so that the channel on which a message is published is returned to the cache instead of being closed.

Messaging integration

Starting with *version 1.4* `RabbitMessagingTemplate`, built on top of `RabbitTemplate`, provides an integration with the Spring Framework messaging abstraction, i.e. `org.springframework.messaging.Message`. This allows you to create the message to send in generic manner.

Sending messages

Introduction

When sending a Message, one can use any of the following methods:

```
void send(Message message) throws AmqpException;

void send(String routingKey, Message message) throws AmqpException;

void send(String exchange, String routingKey, Message message) throws AmqpException;
```

We can begin our discussion with the last method listed above since it is actually the most explicit. It allows an AMQP Exchange name to be provided at runtime along with a routing key. The last parameter is the callback that is responsible for actual creating of the Message instance. An example of using this method to send a Message might look this this:

```
amqpTemplate.send("marketData.topic", "quotes.nasdaq.FOO",
    new Message("12.34".getBytes(), someProperties));
```

The "exchange" property can be set on the template itself if you plan to use that template instance to send to the same exchange most or all of the time. In such cases, the second method listed above may be used instead. The following example is functionally equivalent to the previous one:

```
amqpTemplate.setExchange("marketData.topic");
amqpTemplate.send("quotes.nasdaq.FOO", new Message("12.34".getBytes(), someProperties));
```

If both the "exchange" and "routingKey" properties are set on the template, then the method accepting only the `Message` may be used:

```
amqpTemplate.setExchange("marketData.topic");
amqpTemplate.setRoutingKey("quotes.nasdaq.FOO");
amqpTemplate.send(new Message("12.34".getBytes(), someProperties));
```

A better way of thinking about the exchange and routing key properties is that the explicit method parameters will always override the template's default values. In fact, even if you do not explicitly set those properties on the template, there are always default values in place. In both cases, the default is an empty String, but that is actually a sensible default. As far as the routing key is concerned, it's not always necessary in the first place (e.g. a Fanout Exchange). Furthermore, a Queue may be bound to an Exchange with an empty String. Those are both legitimate scenarios for reliance on the default empty String value for the routing key property of the template. As far as the Exchange name is concerned, the empty String is quite commonly used because the AMQP specification defines the "default Exchange" as having no name. Since all Queues are automatically bound to that default Exchange (which is a Direct Exchange) using their name as the binding value, that second method above can be used for simple point-to-point Messaging to any Queue through the default Exchange. Simply provide the queue name as the "routingKey" - either by providing the method parameter at runtime:

```
RabbitTemplate template = new RabbitTemplate(); // using default no-name Exchange
template.send("queue.helloWorld", new Message("Hello World".getBytes(), someProperties));
```

Or, if you prefer to create a template that will be used for publishing primarily or exclusively to a single Queue, the following is perfectly reasonable:

```
RabbitTemplate template = new RabbitTemplate(); // using default no-name Exchange
template.setRoutingKey("queue.helloWorld"); // but we'll always send to this Queue
template.send(new Message("Hello World".getBytes(), someProperties));
```

Message Builder API

Starting with *version 1.3*, a message builder API is provided by the `MessageBuilder` and `MessagePropertiesBuilder`; they provides a convenient "fluent" means of creating a message or message properties:

```
Message message = MessageBuilder.withBody("foo".getBytes())
 .setContentType(MessageProperties.CONTENT_TYPE_TEXT_PLAIN)
 .setMessageId("123")
 .setHeader("bar", "baz")
 .build();
```

or

```
MessageProperties props = MessagePropertiesBuilder.newInstance()
 .setContentType(MessageProperties.CONTENT_TYPE_TEXT_PLAIN)
 .setMessageId("123")
 .setHeader("bar", "baz")
 .build();
Message message = MessageBuilder.withBody("foo".getBytes())
 .andProperties(props)
 .build();
```

Each of the properties defined on the MessageProperies can be set. Other methods include `setHeader(String key, String value)`, `removeHeader(String key)`, `removeHeaders()`, and `copyProperties(MessageProperties properties)`. Each property setting method has a `set*IfAbsent()` variant. In the cases where a default initial value exists, the method is named `set*IfAbsentOrDefault()`.

Five static methods are provided to create an initial message builder:

```
public static MessageBuilder withBody(byte[] body) ❶

public static MessageBuilder withClonedBody(byte[] body) ❷

public static MessageBuilder withBody(byte[] body, int from, int to) ❸

public static MessageBuilder fromMessage(Message message) ❹

public static MessageBuilder fromClonedMessage(Message message) ❺
```

❶ The message created by the builder will have a body that is a direct reference to the argument.

❷ The message created by the builder will have a body that is a new array containing a copy of bytes in the argument.

❸ The message created by the builder will have a body that is a new array containing the range of bytes from the argument. See `Arrays.copyOfRange()` for more details.

❹ The message created by the builder will have a body that is a direct reference to the body of the argument. The argument's properties are copied to a new `MessageProperties` object.

❺ The message created by the builder will have a body that is a new array containing a copy of the argument's body. The argument's properties are copied to a new `MessageProperties` object.

```
public static MessagePropertiesBuilder newInstance() ❶

public static MessagePropertiesBuilder fromProperties(MessageProperties properties) ❷

public static MessagePropertiesBuilder fromClonedProperties(MessageProperties properties) ❸
```

❶ A new message properties object is initialized with default values.

❷ The builder is initialized with, and `build()` will return, the provided properties object.,

❸ The argument's properties are copied to a new `MessageProperties` object.

With the `RabbitTemplate` implementation of `AmqpTemplate`, each of the `send()` methods has an overloaded version that takes an additional `CorrelationData` object. When publisher confirms are enabled, this object is returned in the callback described in the section called "AmqpTemplate". This allows the sender to correlate a confirm (ack or nack) with the sent message.

Publisher Returns

When the template's `mandatory` property is *true* returned messages are provided by the callback described in the section called "AmqpTemplate".

Starting with *version 1.4* the `RabbitTemplate` supports the SpEL `mandatoryExpression` property, which is evaluated against each request message, as the root evaluation object, resolving to a `boolean` value. Bean references, such as `"@myBean.isMandatory(#root)"` can be used in the expression.

Publisher returns can also be used internally by the `RabbitTemplate` in send and receive operations. See the section called "Reply Timeout" for more information.

Batching

Starting with *version 1.4.2*, the `BatchingRabbitTemplate` has been introduced. This is a subclass of `RabbitTemplate` with an overridden `send` method that batches messages according to the `BatchingStrategy`; only when a batch is complete is the message sent to RabbitMQ.

```
public interface BatchingStrategy {

 MessageBatch addToBatch(String exchange, String routingKey, Message message);

 Date nextRelease();

 Collection<MessageBatch> releaseBatches();

}
```

> **Caution**
>
> Batched data is held in memory; unsent messages can be lost in the event of a system failure.

A `SimpleBatchingStrategy` is provided. It supports sending messages to a single exchange/routing key. It has properties:

- `batchSize` - the number of messages in a batch before it is sent
- `bufferLimit` - the maximum size of the batched message; this will preempt the `batchSize` if exceeded, and cause a partial batch to be sent
- `timeout` - a time after which a partial batch will be sent when there is no new activity adding messages to the batch

The `SimpleBatchingStrategy` formats the batch by preceding each embedded message with a 4 byte binary length. This is communicated to the receiving system by setting the `springBatchFormat` message property to `lengthHeader4`.

> **Important**
>
> Batched messages are automatically de-batched by listener containers (using the `springBatchFormat` message header). Rejecting any message from a batch will cause the entire batch to be rejected.

Receiving messages

Introduction

Message reception is always a little more complicated than sending. There are two ways to receive a `Message`. The simpler option is to poll for a single `Message` at a time with a polling method call. The more complicated yet more common approach is to register a listener that will receive `Messages` on-demand, asynchronously. We will look at an example of each approach in the next two sub-sections.

Polling Consumer

The `AmqpTemplate` itself can be used for polled Message reception. By default, if no message is available, `null` is returned immediately; there is no blocking. Starting with *version 1.5*, you can now set a `receiveTimeout`, in milliseconds, and the receive methods will block for up to that long, waiting for a message. A value less than zero means block indefinitely (or at least until the connection to the broker is lost).

> **Caution**
>
> Since the receive operation creates a new `QueueingConsumer` for each message, this technique is not really appropriate for high-volume environments; consider using an asynchronous consumer, or a `receiveTimeout` of zero for those use cases.

There are two simple *receive* methods available. As with the Exchange on the sending side, there is a method that requires a default queue property having been set directly on the template itself, and there is a method that accepts a queue parameter at runtime.

```
Message receive() throws AmqpException;

Message receive(String queueName) throws AmqpException;
```

Just like in the case of sending messages, the `AmqpTemplate` has some convenience methods for receiving POJOs instead of `Message` instances, and implementations will provide a way to customize the `MessageConverter` used to create the `Object` returned:

```
Object receiveAndConvert() throws AmqpException;

Object receiveAndConvert(String queueName) throws AmqpException;
```

Similar to `sendAndReceive` methods, beginning with *version 1.3*, the `AmqpTemplate` has several convenience `receiveAndReply` methods for synchronously receiving, processing and replying to messages:

```
<R, S> boolean receiveAndReply(ReceiveAndReplyCallback<R, S> callback)
    throws AmqpException;

<R, S> boolean receiveAndReply(String queueName, ReceiveAndReplyCallback<R, S> callback)
  throws AmqpException;

<R, S> boolean receiveAndReply(ReceiveAndReplyCallback<R, S> callback,
 String replyExchange, String replyRoutingKey) throws AmqpException;

<R, S> boolean receiveAndReply(String queueName, ReceiveAndReplyCallback<R, S> callback,
 String replyExchange, String replyRoutingKey) throws AmqpException;

<R, S> boolean receiveAndReply(ReceiveAndReplyCallback<R, S> callback,
  ReplyToAddressCallback<S> replyToAddressCallback) throws AmqpException;

<R, S> boolean receiveAndReply(String queueName, ReceiveAndReplyCallback<R, S> callback,
   ReplyToAddressCallback<S> replyToAddressCallback) throws AmqpException;
```

The `AmqpTemplate` implementation takes care of the *receive* and *reply* phases. In most cases you should provide only an implementation of `ReceiveAndReplyCallback` to perform some business logic for the received message and build a reply object or message, if needed. Note, a `ReceiveAndReplyCallback` may return `null`. In this case no reply is sent and `receiveAndReply` works like the `receive` method. This allows the same queue to be used for a mixture of messages, some of which may not need a reply.

Automatic message (request and reply) conversion is applied only if the provided callback is not an instance of `ReceiveAndReplyMessageCallback` - which provides a raw message exchange contract.

The `ReplyToAddressCallback` is useful for cases requiring custom logic to determine the `replyTo` address at runtime against the received message and reply from the `ReceiveAndReplyCallback`. By default, `replyTo` information in the request message is used to route the reply.

The following is an example of POJO-based receive and reply…

```
boolean received =
        this.template.receiveAndReply(ROUTE, new ReceiveAndReplyCallback<Order, Invoice>() {

                public Invoice handle(Order order) {
                        return processOrder(order);
                }
        });
if (received) {
        log.info("We received an order!");
}
```

Asynchronous Consumer

> **Important**
>
> Spring AMQP also supports annotated-listener endpoints through the use of the `@RabbitListener` annotation and provides an open infrastructure to register endpoints programmatically. This is by far the most convenient way to setup an asynchronous consumer, see the section called “Annotation-driven Listener Endpoints” for more details.

Message Listener

For asynchronous Message reception, a dedicated component (not the `AmqpTemplate`) is involved. That component is a container for a Message consuming callback. We will look at the container and its properties in just a moment, but first we should look at the callback since that is where your application

code will be integrated with the messaging system. There are a few options for the callback starting with an implementation of the `MessageListener` interface:

```
public interface MessageListener {
    void onMessage(Message message);
}
```

If your callback logic depends upon the AMQP Channel instance for any reason, you may instead use the `ChannelAwareMessageListener`. It looks similar but with an extra parameter:

```
public interface ChannelAwareMessageListener {
    void onMessage(Message message, Channel channel) throws Exception;
}
```

MessageListenerAdapter

If you prefer to maintain a stricter separation between your application logic and the messaging API, you can rely upon an adapter implementation that is provided by the framework. This is often referred to as "Message-driven POJO" support. When using the adapter, you only need to provide a reference to the instance that the adapter itself should invoke.

```
MessageListenerAdapter listener = new MessageListenerAdapter(somePojo);
    listener.setDefaultListenerMethod("myMethod");
```

You can subclass the adapter and provide an implementation of `getListenerMethodName()` to dynamically select different methods based on the message. This method has two parameters, the `originalMessage` and `extractedMessage`, the latter being the result of any conversion. By default, a `SimpleMessageConverter` is configured; see the section called “SimpleMessageConverter” for more information and information about other converters available.

Starting with *version 1.4.2*, the original message has properties `consumerQueue` and `consumerTag` which can be used to determine which queue a message was received from.

Starting with *version 1.5*, you can configure a map of consumer queue/tag to method name, to dynamically select the method to call. If no entry is in the map, we fall back to the default listener method.

Container

Now that you’ve seen the various options for the Message-listening callback, we can turn our attention to the container. Basically, the container handles the "active" responsibilities so that the listener callback can remain passive. The container is an example of a "lifecycle" component. It provides methods for starting and stopping. When configuring the container, you are essentially bridging the gap between an AMQP Queue and the `MessageListener` instance. You must provide a reference to the `ConnectionFactory` and the queue name or Queue instance(s) from which that listener should consume Messages. Here is the most basic example using the default implementation, `SimpleMessageListenerContainer` :

```
SimpleMessageListenerContainer container = new SimpleMessageListenerContainer();
container.setConnectionFactory(rabbitConnectionFactory);
container.setQueueNames("some.queue");
container.setMessageListener(new MessageListenerAdapter(somePojo));
```

As an "active" component, it’s most common to create the listener container with a bean definition so that it can simply run in the background. This can be done via XML:

```
<rabbit:listener-container connection-factory="rabbitConnectionFactory">
    <rabbit:listener queues="some.queue" ref="somePojo" method="handle"/>
</rabbit:listener-container>
```

Or, you may prefer to use the @Configuration style which will look very similar to the actual code snippet above:

```
@Configuration
public class ExampleAmqpConfiguration {

    @Bean
    public SimpleMessageListenerContainer messageListenerContainer() {
        SimpleMessageListenerContainer container = new SimpleMessageListenerContainer();
        container.setConnectionFactory(rabbitConnectionFactory());
        container.setQueueName("some.queue");
        container.setMessageListener(exampleListener());
        return container;
    }

    @Bean
    public ConnectionFactory rabbitConnectionFactory() {
        CachingConnectionFactory connectionFactory =
            new CachingConnectionFactory("localhost");
        connectionFactory.setUsername("guest");
        connectionFactory.setPassword("guest");
        return connectionFactory;
    }

    @Bean
    public MessageListener exampleListener() {
        return new MessageListener() {
            public void onMessage(Message message) {
                System.out.println("received: " + message);
            }
        };
    }
}
```

Starting with **RabbitMQ Version 3.2**, the broker now supports consumer priority (see Using Consumer Priorities with RabbitMQ). This is enabled by setting the `x-priority` argument on the consumer. The `SimpleMessageListenerContainer` now supports setting consumer arguments:

```
container.setConsumerArguments(Collections.
<String, Object> singletonMap("x-priority", Integer.valueOf(10)));
```

For convenience, the namespace provides the `priority` attribute on the `listener` element:

```
<rabbit:listener-container connection-factory="rabbitConnectionFactory">
    <rabbit:listener queues="some.queue" ref="somePojo" method="handle" priority="10" />
</rabbit:listener-container>
```

Starting with *version 1.3* the queue(s) on which the container is listening can be modified at runtime; see the section called “Listener Container Queues”.

auto-delete Queues

When a container is configured to listen to `auto-delete` queue(s), or the queue has an `x-expires` option or the Time-To-Live policy is configured on the Broker, the queue is removed by the broker when the container is stopped (last consumer is cancelled). Before *version 1.3*, the container could not be restarted because the queue was missing; the `RabbitAdmin` only automatically redeclares queues etc, when the connection is closed/opens, which does not happen when the container is stopped/started.

Starting with *version 1.3*, the container will now use a `RabbitAdmin` to redeclare any missing queues during startup.

You can also use conditional declaration (the section called “Conditional Declaration”) together with an `auto-startup="false"` admin to defer queue declaration until the container is started.

```
<rabbit:queue id="otherAnon" declared-by="containerAdmin" />

<rabbit:direct-exchange name="otherExchange" auto-delete="true" declared-by="containerAdmin">
 <rabbit:bindings>
  <rabbit:binding queue="otherAnon" key="otherAnon" />
 </rabbit:bindings>
</rabbit:direct-exchange>

<rabbit:listener-container id="container2" auto-startup="false">
 <rabbit:listener id="listener2" ref="foo" queues="otherAnon" admin="containerAdmin" />
</rabbit:listener-container>

<rabbit:admin id="containerAdmin" connection-factory="rabbitConnectionFactory"
 auto-startup="false" />
```

In this case, the queue and exchange are declared by `containerAdmin` which has `auto-startup="false"` so the elements are not declared during context initialization. Also, the container is not started for the same reason. When the container is later started, it uses it's reference to `containerAdmin` to declare the elements.

Batched Messages

Batched messages are automatically de-batched by listener containers (using the `springBatchFormat` message header). Rejecting any message from a batch will cause the entire batch to be rejected. See the section called "Batching" for more information about batching.

Consumer Failure Events

Starting with *version 1.5*, the `SimpleMessageListenerContainer` publishes application events whenever a listener (consumer) experiences a failure of some kind. The event `ListenerContainerConsumerFailedEvent` has the following properties:

- `container` - the listener container where the consumer experienced the problem.
- `reason` - a textual reason for the failure.
- `fatal` - a boolean indicating whether the failure was fatal; with non-fatal exceptions, the container will attempt to restart the consumer, according to the `retryInterval`.
- `throwable` - the `Throwable` that was caught.

These events can be consumed by implementing `ApplicationListener<ListenerContainerConsumerFailedEvent>`.

> **Note**
>
> System-wide events (such as connection failures) will be published by all consumers when `concurrentConsumers` is greater than 1.

If a consumer fails because one if its queues is being used exclusively, by default, as well as publishing the event, a `WARN` log is issued. To change this logging behavior, provide a custom `ConditionalExceptionLogger` in the `SimpleMessageListenerContainer` 's `exclusiveConsumerExceptionLogger` property. See also the section called "Logging Channel Close Events".

Fatal errors are always logged at `ERROR` level; this it not modifiable.

Consumer Tags

Starting with *version 1.4.5*, you can now provide a strategy to generate consumer tags. By default, the consumer tag will be generated by the broker.

```
public interface ConsumerTagStrategy {

    String createConsumerTag(String queue);

}
```

The queue is made available so it can (optionally) be used in the tag.

See the section called “Message Listener Container Configuration”.

Annotation-driven Listener Endpoints

Introduction

Starting with *version 1.4*, the easiest way to receive a message asynchronously is to use the annotated listener endpoint infrastructure. In a nutshell, it allows you to expose a method of a managed bean as a Rabbit listener endpoint.

```
@Component
public class MyService {

    @RabbitListener(queues = "myQueue")
    public void processOrder(String data) {
        ...
    }

}
```

The idea of the example above is that, whenever a message is available on the `org.springframework.amqp.core.Queue` "myQueue", the `processOrder` method is invoked accordingly (in this case, with the payload of the message).

The annotated endpoint infrastructure creates a message listener container behind the scenes for each annotated method, using a `RabbitListenerContainerFactory`.

In the example above, `myQueue` must already exist and be bound to some exchange. Starting with *version 1.5.0*, the queue can be declared and bound automatically, as long as a `RabbitAdmin` exists in the application context.

```
@Component
public class MyService {

  @RabbitListener(bindings = @QueueBinding(
        value = @Queue(value = "myQueue", durable = "true"),
        exchange = @Exchange(value = "auto.exch"),
        key = "orderRoutingKey")
  )
  public void processOrder(String data) {
    ...
  }

  @RabbitListener(bindings = @QueueBinding(
        value = @Queue(),
        exchange = @Exchange(value = "auto.exch"),
        key = "invoiceRoutingKey")
  )
  public void processInvoice(String data) {
    ...
  }

}
```

In the first example, a queue `myQueue` will be declared automatically (durable) together with the exchange, if needed, and bound to the exchange with the routing key. In the second example, an anonymous (exclusive, auto-delete) queue will be declared and bound. Multiple `QueueBinding` entries can be provided, allowing the listener to listen to multiple queues.

Enable listener endpoint annotations

To enable support for `@RabbitListener` annotations add `@EnableRabbit` to one of your `@Configuration` classes.

```
@Configuration
@EnableRabbit
public class AppConfig {

    @Bean
    public SimpleRabbitListenerContainerFactory rabbitListenerContainerFactory() {
        SimpleRabbitListenerContainerFactory factory = new SimpleRabbitListenerContainerFactory();
        factory.setConnectionFactory(connectionFactory());
        factory.setConcurrentConsumers(3);
        factory.setMaxConcurrentConsumers(10);
        return factory;
    }
}
```

By default, the infrastructure looks for a bean named `rabbitListenerContainerFactory` as the source for the factory to use to create message listener containers. In this case, and ignoring the RabbitMQ infrastructure setup, the `processOrder` method can be invoked with a core poll size of 3 threads and a maximum pool size of 10 threads.

It is possible to customize the listener container factory to use per annotation or an explicit default can be configured by implementing the `RabbitListenerConfigurer` interface. The default is only required if at least one endpoint is registered without a specific container factory. See the javadoc for full details and examples.

If you prefer XML configuration, use the `<rabbit:annotation-driven>` element.

```
<rabbit:annotation-driven/>

<bean id="rabbitListenerContainerFactory"
      class="org.springframework.amqp.rabbit.config.SimpleRabbitListenerContainerFactory">
    <property name="connectionFactory" ref="connectionFactory"/>
    <property name="concurrentConsumers" value="3"/>
    <property name="maxConcurrentConsumers" value="10"/>
</bean>
```

Message Conversion for Annotated Methods

There are two conversion steps in the pipeline before invoking the listener. The first uses a `MessageConverter` to convert the incoming Spring AMQP `Message` to a *spring-messaging* `Message`. When the target method is invoked, the message payload is converted, if necessary, to the method parameter type.

The default `MessageConverter` for the first step is a Spring AMQP `SimpleMessageConverter` that handles conversion to `String` and `java.io.Serializable` objects; all others remain as a `byte[]`. In the following discussion, we call this the *message converter*.

The default converter for the second step is a `GenericMessageConverter` which delegates to a conversion service (an instance of `DefaultFormattingConversionService`). In the following discussion, we call this the *method argument converter*.

To change the *message converter*, simply add it as a property to the container factory bean:

```
@Bean
public SimpleRabbitListenerContainerFactory rabbitListenerContainerFactory() {
    SimpleRabbitListenerContainerFactory factory = new SimpleRabbitListenerContainerFactory();
    ...
    factory.setMessageConverter(new Jackson2JsonMessageConverter());
    ...
    return factory;
}
```

This configures a Jackson2 converter that expects header information to be present to guide the conversion.

You can also consider a `ContentTypeDelegatingMessageConverter` which can handle conversion of different content types.

In most cases, it is not necessary to customize the *method argument converter* unless, for example, you want to use a custom `ConversionService`.

If you wish to customize the *method argument converter*, you can do so as follows:

```
@Configuration
@EnableRabbit
public class AppConfig implements RabbitListenerConfigurer {

    ...

    @Bean
 public DefaultMessageHandlerMethodFactory myHandlerMethodFactory() {
     DefaultMessageHandlerMethodFactory factory = new DefaultMessageHandlerMethodFactory();
     factory.setMessageConverter(new GenericMessageConverter(myConversionService()));
     return factory;
    }

    @Bean
    public ConversionService myConversionService() {
     DefaultConversionService conv = new DefaultConversionService();
     conv.addConverter(mySpecialConverter());
     return conv;
    }

    @Override
    public void configureRabbitListeners(RabbitListenerEndpointRegistrar registrar) {
     registrar.setMessageHandlerMethodFactory(myHandlerMethodFactory());
    }

    ...

}
```

> **Important**
>
> for multi-method listeners (see the section called “Multi-Method Listeners”), the method selection is based on the payload of the message **after the message conversion**; the *method argument converter* is only called after the method has been selected.

Programmatic Endpoint Registration

`RabbitListenerEndpoint` provides a model of a Rabbit endpoint and is responsible for configuring the container for that model. The infrastructure allows you to configure endpoints programmatically in addition to the ones that are detected by the `RabbitListener` annotation.

```
@Configuration
@EnableRabbit
public class AppConfig implements RabbitListenerConfigurer {

    @Override
    public void configureRabbitListeners(RabbitListenerEndpointRegistrar registrar) {
        SimpleRabbitListenerEndpoint endpoint = new SimpleRabbitListenerEndpoint();
        endpoint.setQueueNames("anotherQueue");
        endpoint.setMessageListener(message -> {
            // processing
        });
        registrar.registerEndpoint(endpoint);
    }
}
```

In the example above, we used `SimpleRabbitListenerEndpoint` which provides the actual `MessageListener` to invoke but you could just as well build your own endpoint variant describing a custom invocation mechanism.

It should be noted that you could just as well skip the use of `@RabbitListener` altogether and only register your endpoints programmatically through RabbitListenerConfigurer.

Annotated Endpoint Method Signature

So far, we have been injecting a simple String in our endpoint but it can actually have a very flexible method signature. Let's rewrite it to inject the `Order` with a custom header:

```
@Component
public class MyService {

    @RabbitListener(queues = "myQueue")
    public void processOrder(Order order, @Header("order_type") String orderType) {
        ...
    }
}
```

These are the main elements you can inject in listener endpoints:

The raw `org.springframework.amqp.core.Message`.

The `com.rabbitmq.client.Channel` on which the message was received

The `org.springframework.messaging.Message` representing the incoming AMQP message. Note that this message holds both the custom and the standard headers (as defined by `AmqpHeaders`).

`@Header`-annotated method arguments to extract a specific header value, including standard AMQP headers.

`@Headers`-annotated argument that must also be assignable to `java.util.Map` for getting access to all headers.

A non-annotated element that is not one of the supported types (i.e. `Message` and `Channel`) is considered to be the payload. You can make that explicit by annotating the parameter with `@Payload`. You can also turn on validation by adding an extra `@Valid`.

The ability to inject Spring's Message abstraction is particularly useful to benefit from all the information stored in the transport-specific message without relying on transport-specific API.

```
@RabbitListener(queues = "myQueue")
public void processOrder(Message<Order> order) { ...
}
```

Handling of method arguments is provided by `DefaultMessageHandlerMethodFactory` which can be further customized to support additional method arguments. The conversion and validation support can be customized there as well.

For instance, if we want to make sure our Order is valid before processing it, we can annotate the payload with `@Valid` and configure the necessary validator as follows:

```
@Configuration
@EnableRabbit
public class AppConfig implements RabbitListenerConfigurer {

    @Override
    public void configureRabbitListeners(RabbitListenerEndpointRegistrar registrar) {
        registrar.setMessageHandlerMethodFactory(myHandlerMethodFactory());
    }

    @Bean
    public DefaultMessageHandlerMethodFactory myHandlerMethodFactory() {
        DefaultMessageHandlerMethodFactory factory = new DefaultMessageHandlerMethodFactory();
        factory.setValidator(myValidator());
        return factory;
    }
}
```

Listening to Multiple Queues

When using the `queues` attribute, you can specify that the associated container can listen to multiple queues. You can use a `@Header` annotation to make the queue name from which a message was received available to the POJO method:

```
@Component
public class MyService {

    @RabbitListener(queues = { "queue1", "queue2" } )
    public void processOrder(String data, @Header(AmqpHeaders.CONSUMER_QUEUE) String queue) {
        ...
    }

}
```

Starting with *version 1.5*, you can externalize the queue names using property placeholders, and SpEL:

```
@Component
public class MyService {

    @RabbitListener(queues = "#{'${property.with.comma.delimited.queue.names}'.split(',')}" )
    public void processOrder(String data, @Header(AmqpHeaders.CONSUMER_QUEUE) String queue) {
        ...
    }

}
```

Prior to *version 1.5*, only a single queue could be specified this way; each queue needed a separate property.

Reply Management

The existing support in `MessageListenerAdapter` already allows your method to have a non-void return type. When that's the case, the result of the invocation is encapsulated in a message sent either in the address specified in the `ReplyToAddress` header of the original message or in the default address configured on the listener. That default address can now be set using the `@SendTo` annotation of the messaging abstraction.

Assuming our `processOrder` method should now return an `OrderStatus`, it is possible to write it as follow to automatically send a reply:

```
@RabbitListener(destination = "myQueue")
@SendTo("status")
public OrderStatus processOrder(Order order) {
    // order processing
    return status;
}
```

If you need to set additional headers in a transport-independent manner, you could return a `Message` instead, something like:

```
@RabbitListener(destination = "myQueue")
@SendTo("status")
public Message<OrderStatus> processOrder(Order order) {
    // order processing
    return MessageBuilder
        .withPayload(status)
        .setHeader("code", 1234)
        .build();
}
```

The `@SendTo` value is assumed as a reply `exchange` and `routingKey` pair following the pattern `exchange/routingKey`, where one of those parts can be omitted. The valid values are:

`foo/bar` - the replyTo exchange and routingKey.

`foo/` - the replyTo exchange and default (empty) routingKey.

`bar` or `/bar` - the replyTo routingKey and default (empty) exchange.

`/` or empty - the replyTo default exchange and default routingKey.

Also `@SendTo` can be used without a `value` attribute. This case is equal to an empty sendTo pattern. `@SendTo` is only used if the inbound message does not have a `replyToAddress` property.

Starting with *version 1.5*, the `@SendTo` value can be a SpEL Expression, for example…

```
@RabbitListener(queues = "test.sendTo.spel")
@SendTo("#{spelReplyTo}")
public String capitalizeWithSendToSpel(String foo) {
    return foo.toUpperCase();
}
...
@Bean
public String spelReplyTo() {
    return "test.sendTo.reply.spel";
}
```

The expression must evaluate to a `String`, which can be a simple queue name (sent to the default exchange) or with the form `exchange/routingKey` as discussed above. The expression is evaluated once, during context initialization. For dynamic reply routing, the message sender should include a `reply_to` message property.

Multi-Method Listeners

Starting with *version 1.5.0*, the `@RabbitListener` annotation can now be specified at the class level. Together with the new `@RabbitHandler` annotation, this allows a single listener to invoke different methods, based on the payload type of the incoming message. This is best described using an example:

```
@RabbitListener(id="multi", queues = "someQueue")
public class MultiListenerBean {

    @RabbitHandler
    @SendTo("my.reply.queue")
    public String bar(Bar bar) {
        ...
    }

    @RabbitHandler
    public String baz(Baz baz) {
        ...
    }

    @RabbitHandler
    public String qux(@Header("amqp_receivedRoutingKey") String rk, @Payload Qux qux) {
        ...
    }

}
```

In this case, the individual `@RabbitHandler` methods are invoked if the converted payload is a `Bar`, `Baz` or `Qux`. It is important to understand that the system must be able to identify a unique method based on the payload type. The type is checked for assignability to a single parameter that has no annotations, or is annotated with the `@Payload` annotation. Notice that the same method signatures apply as discussed in the method-level `@RabbitListener` described above.

Notice that the `@SendTo` must be specified on each method (if needed); it is not supported at the class level.

Container Management

Containers created for annotations are not registered with the application context. You can obtain a collection of all containers by invoking `getListenerContainers()` on the `RabbitListenerEndpointRegistry` bean. You can then iterate over this collection, for example, to stop/start all containers or invoke the `Lifecycle` methods on the registry itself which will invoke the operations on each container.

You can also get a reference to an individual container using its `id`, using `getListenerContainer(String id)`; for example `registry.getListenerContainer("multi")` for the container created by the snippet above.

Starting with version *1.5.2*, you can obtain the `id`s of the registered containers with `getListenerContainerIds()`.

Starting with *version 1.5*, you can now assign a `group` to the container on the `RabbitListener` endpoint. This provides a mechanism to get a reference to a subset of containers; adding a `group` attribute causes a bean of type `Collection<MessageListenerContainer>` to be registered with the context with the group name.

Threading and Asynchronous Consumers

A number of different threads are involved with asynchronous consumers.

Threads from the `TaskExecutor` configured in the `SimpleMessageListener` are used to invoke the `MessageListener` when a new message is delivered by `RabbitMQ Client`. If not configured, a `SimpleAsyncTaskExecutor` is used. If a pooled executor is used, ensure the pool size is sufficient to handle the configured concurrency.

The `Executor` configured in the `CachingConnectionFactory` is passed into the `RabbitMQ Client` when creating the connection, and its threads are used to deliver new messages to the listener container. At the time of writing, if this is not configured, the client uses an internal thread pool executor with a pool size of 5.

The `RabbitMQ client` uses a `ThreadFactory` to create threads for low-level I/O (socket) operations. To modify this factory, you need to configure the underlying RabbitMQ `ConnectionFactory`, as discussed in the section called “Configuring the Underlying Client Connection Factory”.

Message Converters

Introduction

The `AmqpTemplate` also defines several methods for sending and receiving Messages that will delegate to a `MessageConverter`. The `MessageConverter` itself is quite straightforward. It provides a single method for each direction: one for converting **to** a Message and another for converting **from** a Message. Notice that when converting to a Message, you may also provide properties in addition to the object. The "object" parameter typically corresponds to the Message body.

```
public interface MessageConverter {

    Message toMessage(Object object, MessageProperties messageProperties)
            throws MessageConversionException;

    Object fromMessage(Message message) throws MessageConversionException;

}
```

The relevant Message-sending methods on the `AmqpTemplate` are listed below. They are simpler than the methods we discussed previously because they do not require the `Message` instance. Instead, the `MessageConverter` is responsible for "creating" each `Message` by converting the provided object to the byte array for the `Message` body and then adding any provided `MessageProperties`.

```
void convertAndSend(Object message) throws AmqpException;

void convertAndSend(String routingKey, Object message) throws AmqpException;

void convertAndSend(String exchange, String routingKey, Object message)
    throws AmqpException;

void convertAndSend(Object message, MessagePostProcessor messagePostProcessor)
    throws AmqpException;

void convertAndSend(String routingKey, Object message,
    MessagePostProcessor messagePostProcessor) throws AmqpException;

void convertAndSend(String exchange, String routingKey, Object message,
    MessagePostProcessor messagePostProcessor) throws AmqpException;
```

On the receiving side, there are only two methods: one that accepts the queue name and one that relies on the template's "queue" property having been set.

```
Object receiveAndConvert() throws AmqpException;

Object receiveAndConvert(String queueName) throws AmqpException;
```

> **Note**
>
> The `MessageListenerAdapter` mentioned in the section called “Asynchronous Consumer” also uses a `MessageConverter`.

SimpleMessageConverter

The default implementation of the `MessageConverter` strategy is called `SimpleMessageConverter`. This is the converter that will be used by an instance of RabbitTemplate if you do not explicitly configure an alternative. It handles text-based content, serialized Java objects, and simple byte arrays.

Converting From a Message

If the content type of the input Message begins with "text" (e.g. "text/plain"), it will also check for the content-encoding property to determine the charset to be used when converting the Message body byte array to a Java String. If no content-encoding property had been set on the input Message, it will use the "UTF-8" charset by default. If you need to override that default setting, you can configure an instance of `SimpleMessageConverter`, set its "defaultCharset" property and then inject that into a `RabbitTemplate` instance.

If the content-type property value of the input Message is set to "application/x-java-serialized-object", the `SimpleMessageConverter` will attempt to deserialize (rehydrate) the byte array into a Java object. While that might be useful for simple prototyping, it's generally not recommended to rely on Java serialization since it leads to tight coupling between the producer and consumer. Of course, it also rules out usage of non-Java systems on either side. With AMQP being a wire-level protocol, it would be unfortunate to lose much of that advantage with such restrictions. In the next two sections, we'll explore some alternatives for passing rich domain object content without relying on Java serialization.

For all other content-types, the `SimpleMessageConverter` will return the Message body content directly as a byte array.

Converting To a Message

When converting to a Message from an arbitrary Java Object, the `SimpleMessageConverter` likewise deals with byte arrays, Strings, and Serializable instances. It will convert each of these to bytes (in the case of byte arrays, there is nothing to convert), and it will set the content-type property accordingly. If the Object to be converted does not match one of those types, the Message body will be null.

JsonMessageConverter and Jackson2JsonMessageConverter

As mentioned in the previous section, relying on Java serialization is generally not recommended. One rather common alternative that is more flexible and portable across different languages and platforms is JSON (JavaScript Object Notation). Two implementations are available and can be configured on any `RabbitTemplate` instance to override its usage of the `SimpleMessageConverter` default. The `JsonMessageConverter` which uses the `org.codehaus.jackson` 1.x library and `Jackson2JsonMessageConverter` which uses the `com.fasterxml.jackson` 2.x library.

```
<bean class="org.springframework.amqp.rabbit.core.RabbitTemplate">
    <property name="connectionFactory" ref="rabbitConnectionFactory"/>
    <property name="messageConverter">
        <bean class="org.springframework.amqp.support.converter.JsonMessageConverter">
            <!-- if necessary, override the DefaultClassMapper -->
            <property name="classMapper" ref="customClassMapper"/>
        </bean>
    </property>
</bean>
```

```
<bean class="org.springframework.amqp.rabbit.core.RabbitTemplate">
    <property name="connectionFactory" ref="rabbitConnectionFactory"/>
    <property name="messageConverter">
        <bean class="org.springframework.amqp.support.converter.Jackson2JsonMessageConverter">
            <!-- if necessary, override the DefaultClassMapper -->
            <property name="classMapper" ref="customClassMapper"/>
        </bean>
    </property>
</bean>
```

As shown above, the `JsonMessageConverter` and `Jackson2JsonMessageConverter` uses a `DefaultClassMapper` by default. Type information is added to (and retrieved from) the `MessageProperties`. If an inbound message does not contain type information in the `MessageProperties`, but you know the expected type, you can configure a static type using the `defaultType` property

```
<bean id="jsonConverterWithDefaultType"
      class="o.s.amqp.support.converter.JsonMessageConverter">
    <property name="classMapper">
        <bean class="org.springframework.amqp.support.converter.DefaultClassMapper">
            <property name="defaultType" value="foo.PurchaseOrder"/>
        </bean>
    </property>
</bean>
```

```
<bean id="jsonConverterWithDefaultType"
      class="o.s.amqp.support.converter.Jackson2JsonMessageConverter">
    <property name="classMapper">
        <bean class="org.springframework.amqp.support.converter.DefaultClassMapper">
            <property name="defaultType" value="foo.PurchaseOrder"/>
        </bean>
    </property>
</bean>
```

MarshallingMessageConverter

Yet another option is the `MarshallingMessageConverter`. It delegates to the Spring OXM library's implementations of the `Marshaller` and `Unmarshaller` strategy interfaces. You can read more about that library here. In terms of configuration, it's most common to provide the constructor argument only since most implementations of `Marshaller` will also implement `Unmarshaller`.

```
<bean class="org.springframework.amqp.rabbit.core.RabbitTemplate">
    <property name="connectionFactory" ref="rabbitConnectionFactory"/>
    <property name="messageConverter">
        <bean class="org.springframework.amqp.support.converter.MarshallingMessageConverter">
            <constructor-arg ref="someImplemenationOfMarshallerAndUnmarshaller"/>
        </bean>
    </property>
</bean>
```

ContentTypeDelegatingMessageConverter

This class was introduced in *version 1.4.2* and allows delegation to a specific `MessageConverter` based on the content type property in the `MessageProperties`. By default, it will delegate to a `SimpleMessageConverter` if there is no `contentType` property, or a value that matches none of the configured converters.

```
<bean id="contentTypeConverter" class="ContentTypeDelegatingMessageConverter">
    <property name="delegates">
        <map>
            <entry key="application/json" value-ref="jsonMessageConverter" />
            <entry key="application/xml" value-ref="xmlMessageConverter" />
        </map>
    </property>
</bean>
```

Message Properties Converters

The `MessagePropertiesConverter` strategy interface is used to convert between the Rabbit Client `BasicProperties` and Spring AMQP `MessageProperties`. The default implementation (`DefaultMessagePropertiesConverter`) is usually sufficient for most purposes but you can implement your own if needed. The default properties converter will convert `BasicProperties` elements of type `LongString` to `String` s when the size is not greater than `1024` bytes. Larger `LongString` s are returned as a `DataInputStream. This limit can be overridden with a constructor argument.

Modifying Messages - Compression and More

A number of extension points exist where you can perform some processing on a message, either before it is sent to RabbitMQ, or immediately after it is received.

As can be seen in the section called “Message Converters”, one such extension point is in the `AmqpTemplate` `convertAndReceive` operations, where you can provide a `MessagePostProcessor`. For example, after your POJO has been converted, the `MessagePostProcessor` enables you to set custom headers or properties on the `Message`.

Starting with *version 1.4.2*, additional extension points have been added to the `RabbitTemplate` - `setBeforePublishPostProcessors()` and `setAfterReceivePostProcessors()`. The first enables a post processor to run immediately before sending to RabbitMQ. When using batching (see the section called “Batching”), this is invoked after the batch is assembled and before the batch is sent. The second is invoked immediately after a message is received.

These extension points are used for such features as compression and, for this purpose, several `MessagePostProcessor` s are provided:

- GZipPostProcessor
- ZipPostProcessor

for compressing messages before sending, and

- GUnzipPostProcessor
- UnzipPostProcessor

for decompressing received messages.

Similarly, the `SimpleMessageListenerContainer` also has a `setAfterReceivePostProcessors()` method, allowing the decompression to be performed after messages are received by the container.

Request/Reply Messaging

Introduction

The `AmqpTemplate` also provides a variety of `sendAndReceive` methods that accept the same argument options that you have seen above for the one-way send operations (exchange, routingKey, and Message). Those methods are quite useful for request/reply scenarios since they handle the configuration of the necessary "reply-to" property before sending and can listen for the reply message on an exclusive Queue that is created internally for that purpose.

Similar request/reply methods are also available where the `MessageConverter` is applied to both the request and reply. Those methods are named `convertSendAndReceive`. See the Javadoc of `AmqpTemplate` for more detail.

Starting with *version 1.5.0*, each of the `sendAndReceive` method variants has an overloaded version that takes `CorrelationData`. Together with a properly configured connection factory, this enables the receipt of publisher confirms for the send side of the operation. See the section called “Publisher Confirms and Returns” for more information.

Reply Timeout

By default, the send and receive methods will timeout after 5 seconds and return null. This can be modified by setting the `replyTimeout` property. Starting with *version 1.5*, if you set the `mandatory` property to true (or the `mandatory-expression` evaluates to `true` for a particular message), if the message cannot be delivered to a queue an `AmqpMessageReturnedException` will be thrown. This exception has `returnedMessage`, `replyCode`, `replyText` properties, as well as the `exchange` and `routingKey` used for the send.

> **Note**
>
> This feature uses publisher returns and is enabled by setting `publisherReturns` to true on the `CachingConnectionFactory` (see the section called “Publisher Confirms and Returns”). Also, you must not have registered your own `ReturnCallback` with the `RabbitTemplate`.

RabbitMQ Direct reply-to

> **Important**
>
> Starting with *version 3.4.0*, the RabbitMQ server now supports Direct reply-to; this eliminates the main reason for a fixed reply queue (to avoid the need to create a temporary queue for each request). Starting with **Spring AMQP version 1.4.1** Direct reply-to will be used by default (if supported by the server) instead of creating temporary reply queues. When no `replyQueue` is provided (or it is set with the name `amq.rabbitmq.reply-to`), the `RabbitTemplate` will automatically detect whether Direct reply-to is supported and either use it or fall back to using a temporary reply queue. When using Direct reply-to, a `reply-listener` is not required and should not be configured.

Reply listeners are still supported with named queues (other than `amq.rabbitmq.reply-to`), allowing control of reply concurrency etc.

Message Correlation With A Reply Queue

When using a fixed reply queue (other than `amq.rabbitmq.reply-to`), it is necessary to provide correlation data so that replies can be correlated to requests. See RabbitMQ Remote Procedure Call (RPC). By default, the standard `correlationId` property will be used to hold the correlation data. However, if you wish to use a custom property to hold correlation data, you can set the `correlation-key` attribute on the <rabbit-template/>. Explicitly setting the attribute to `correlationId` is the same as omitting the attribute. Of course, the client and server must use the same header for correlation data.

> **Note**
>
> Spring AMQP version 1.1 used a custom property `spring_reply_correlation` for this data. If you wish to revert to this behavior with the current version, perhaps to maintain compatibility with another application using 1.1, you must set the attribute to `spring_reply_correlation`.

Reply Listener Container

When using RabbitMQ versions prior to *3.4.0*, a new temporary queue is used for each reply. However, a single reply queue can be configured on the template, which can be more efficient, and also allows you to set arguments on that queue. In this case, however, you must also provide a <reply-listener/> sub element. This element provides a listener container for the reply queue, with the template being the listener. All of the the section called “Message Listener Container Configuration” attributes allowed on a <listener-container/> are allowed on the element, except for connection-factory and message-converter, which are inherited from the template’s configuration.

```
<rabbit:template id="amqpTemplate"
        connection-factory="connectionFactory"
        reply-queue="replies"
        reply-address="replyEx/routeReply">
    <rabbit:reply-listener/>
</rabbit:template>
```

While the container and template share a connection factory, they do not share a channel and therefore requests and replies are not performed within the same transaction (if transactional).

> **Note**
>
> Prior to *version 1.5.0*, the `reply-address` attribute was not available, replies were always routed using the default exchange and the `reply-queue` name as the routing key. This is still the default but you can now specify the new `reply-address` attribute. The `reply-address` can contain an address with the form `<exchange>/<routingKey>` and the reply will be routed to the specified **exchange** and routed to a queue bound with the **routing key**. The `reply-address` has precedence over `reply-queue`. The `<reply-listener>` must be configured as a separate `<listener-container>` component, when only `reply-address` is in use, anyway `reply-address` and `reply-queue` (or `queues` attribute on the `<listener-container>`) must refer to the same queue logically.

With this configuration, a `SimpleListenerContainer` is used to receive the replies; with the `RabbitTemplate` being the `MessageListener`. When defining a template with the `<rabbit:template/>` namespace element, as shown above, the parser defines the container and wires in the template as the listener.

> **Note**
>
> When the template does not use a fixed `replyQueue` (or is using Direct reply-to - see the section called “RabbitMQ Direct reply-to”) a listener container is not needed. Direct `reply-to` is the preferred mechanism when using RabbitMQ *3.4.0* or later.

If you define your `RabbitTemplate` as a `<bean/>`, or using an `@Configuration` class to define it as an `@Bean`, or when creating the template programmatically, you will need to define and wire up the reply listener container yourself. If you fail to do this, the template will never receive the replies and will eventually time out and return null as the reply to a call to a `sendAndReceive` method.

Starting with *version 1.5*, the `RabbitTemplate` will detect if it has been configured as a `MessageListener` to receive replies. If not, attempts to send and receive messages with a reply address will fail with an `IllegalStateException` (because the replies will never be received).

Further, if a simple `replyAddress` (queue name) is used, the reply listener container will verify that it is listening to a queue with the same name. This check cannot be performed if the reply address is an exchange and routing key and a debug log message will be written.

> **Important**
>
> When wiring the reply listener and template yourself, it is important to ensure that the template’s `replyQueue` and the container’s `queues` (or `queueNames`) properties refer to the same queue. The template inserts the reply queue into the outbound message `replyTo` property.

The following are examples of how to manually wire up the beans.

```
<bean id="amqpTemplate" class="org.springframework.amqp.rabbit.core.RabbitTemplate">
    <constructor-arg ref="connectionFactory" />
    <property name="exchange" value="foo.exchange" />
    <property name="routingKey" value="foo" />
    <property name="replyQueue" ref="replyQ" />
    <property name="replyTimeout" value="600000" />
</bean>

<bean class="org.springframework.amqp.rabbit.listener.SimpleMessageListenerContainer">
    <constructor-arg ref="connectionFactory" />
    <property name="queues" ref="replyQ" />
    <property name="messageListener" ref="amqpTemplate" />
</bean>

<rabbit:queue id="replyQ" name="my.reply.queue" />
```

```
@Bean
public RabbitTemplate amqpTemplate() {
    RabbitTemplate rabbitTemplate = new RabbitTemplate(connectionFactory());
    rabbitTemplate.setMessageConverter(msgConv());
    rabbitTemplate.setReplyQueue(replyQueue());
    rabbitTemplate.setReplyTimeout(60000);
    return rabbitTemplate;
}

@Bean
public SimpleMessageListenerContainer replyListenerContainer() {
    SimpleMessageListenerContainer container = new SimpleMessageListenerContainer();
    container.setConnectionFactory(connectionFactory());
    container.setQueues(replyQueue());
    container.setMessageListener(amqpTemplate());
    return container;
}

@Bean
public Queue replyQueue() {
    return new Queue("my.reply.queue");
}
```

A complete example of a `RabbitTemplate` wired with a fixed reply queue, together with a "remote" listener container that handles the request and returns the reply is shown in this test case.

> **Important**
>
> When the reply times out (`replyTimeout`), the `sendAndReceive()` methods return null.

Prior to *version 1.3.6*, late replies for timed out messages were simply logged. Now, if a late reply is received, it is rejected (the template throws an `AmqpRejectAndDontRequeueException`). If the reply queue is configured to send rejected messages to a dead letter exchange, the reply can be retrieved for later analysis. Simply bind a queue to the configured dead letter exchange with a routing key equal to the reply queue's name.

Refer to the RabbitMQ Dead Letter Documentation for more information about configuring dead lettering. You can also take a look at the `FixedReplyQueueDeadLetterTests` test case for an example.

Spring Remoting with AMQP

The Spring Framework has a general remoting capability, allowing Remote Procedure Calls (RPC) using various transports. Spring-AMQP supports a similar mechanism with a `AmqpProxyFactoryBean` on the client and a `AmqpInvokerServiceExporter` on the server. This provides RPC over AMQP. On the client side, a `RabbitTemplate` is used as described above; on the server side, the invoker (configured as a `MessageListener`) receives the message, invokes the configured service, and returns the reply using the inbound message's `replyTo` information.

The client factory bean can be injected into any bean (using its `serviceInterface`); the client can then invoke methods on the proxy, resulting in remote execution over AMQP.

> **Note**
>
> With the default `MessageConverter` s, the method parameters and returned value must be instances of `Serializable`.

On the server side, the `AmqpInvokerServiceExporter` has both `AmqpTemplate` and `MessageConverter` properties. Currently, the template's `MessageConverter` is not used. If you

need to supply a custom message converter, then you should provide it using the `messageConverter` property. On the client side, a custom message converter can be added to the `AmqpTemplate` which is provided to the `AmqpProxyFactoryBean` using its `amqpTemplate` property.

Sample client and server configurations are shown below.

```
<bean id="client"
 class="org.springframework.amqp.remoting.client.AmqpProxyFactoryBean">
 <property name="amqpTemplate" ref="template" />
 <property name="serviceInterface" value="foo.ServiceInterface" />
</bean>

<rabbit:connection-factory id="connectionFactory" />

<rabbit:template id="template" connection-factory="connectionFactory" reply-timeout="2000"
 routing-key="remoting.binding" exchange="remoting.exchange" />

<rabbit:admin connection-factory="connectionFactory" />

<rabbit:queue name="remoting.queue" />

<rabbit:direct-exchange name="remoting.exchange">
 <rabbit:bindings>
  <rabbit:binding queue="remoting.queue" key="remoting.binding" />
 </rabbit:bindings>
</rabbit:direct-exchange>
```

```
<bean id="listener"
 class="org.springframework.amqp.remoting.service.AmqpInvokerServiceExporter">
 <property name="serviceInterface" value="foo.ServiceInterface" />
 <property name="service" ref="service" />
 <property name="amqpTemplate" ref="template" />
</bean>

<bean id="service" class="foo.ServiceImpl" />

<rabbit:connection-factory id="connectionFactory" />

<rabbit:template id="template" connection-factory="connectionFactory" />

<rabbit:queue name="remoting.queue" />

<rabbit:listener-container connection-factory="connectionFactory">
 <rabbit:listener ref="listener" queue-names="remoting.queue" />
</rabbit:listener-container>
```

Important

The `AmqpInvokerServiceExporter` can only process properly formed messages, such as those sent from the `AmqpProxyFactoryBean`. If it receives a message that it cannot interpret, a serialized `RuntimeException` will be sent as a reply. If the message has no `replyToAddress` property, the message will be rejected and permanently lost if no Dead Letter Exchange has been configured.

Note

By default, if the request message cannot be delivered, the calling thread will eventually timeout and a `RemoteProxyFailureException` will be thrown. The timeout is 5 seconds by default, and can be modified by setting the `replyTimeout` property on the `RabbbitTemplate`. Starting with *version 1.5*, setting the `mandatory` property to true, and enabling returns on the connection factory (see the section called “Publisher Confirms and Returns”), the calling thread will throw

an `AmqpMessageReturnedException`. See the section called “Reply Timeout” for more information.

Configuring the broker

Introduction

The AMQP specification describes how the protocol can be used to configure Queues, Exchanges and Bindings on the broker. These operations which are portable from the 0.8 specification and higher are present in the AmqpAdmin interface in the org.springframework.amqp.core package. The RabbitMQ implementation of that class is RabbitAdmin located in the org.springframework.amqp.rabbit.core package.

The AmqpAdmin interface is based on using the Spring AMQP domain abstractions and is shown below:

```
public interface AmqpAdmin {

    // Exchange Operations

    void declareExchange(Exchange exchange);

    void deleteExchange(String exchangeName);

    // Queue Operations

    Queue declareQueue();

    String declareQueue(Queue queue);

    void deleteQueue(String queueName);

    void deleteQueue(String queueName, boolean unused, boolean empty);

    void purgeQueue(String queueName, boolean noWait);

    // Binding Operations

    void declareBinding(Binding binding);

    void removeBinding(Binding binding);

    Properties getQueueProperties(String queueName);

}
```

The `getQueueProperties()` method returns some limited information about the queue (message count and consumer count). The keys for the properties returned are available as constants in the `RabbitTemplate` (`QUEUE_NAME`, `QUEUE_MESSAGE_COUNT`, `QUEUE_CONSUMER_COUNT`). The RabbitMQ REST API provides much more information in the `QueueInfo` object.

The no-arg `declareQueue()` method defines a queue on the broker with a name that is automatically generated. The additional properties of this auto-generated queue are `exclusive=true`, `autoDelete=true`, and `durable=false`.

The `declareQueue(Queue queue)` method takes a `Queue` object and returns the name of the declared queue. If the provided `Queue`'s `name` property is an empty String, the broker declares the queue with a generated name and that name is returned to the caller. The `Queue` object itself is not changed. This functionality can only be used programmatically by invoking the `RabbitAdmin` directly. It is not supported for auto-declaration by the admin by defining a queue declaratively in the application context.

This is in contrast to an `AnonymousQueue` where the framework generates a unique (`UUID`) name and sets `durable` to `false` and `exlusive`, `autoDelete` to `true`. A `<rabbit:queue/>` with an empty, or missing, `name` attribute will always create an `AnonymousQueue`.

See the section called “AnonymousQueue” to understand why `AnonymousQueue` is preferred over broker-generated queue names, as well as how to control the format of the name. Declarative queues must have fixed names because they might be referenced elsewhere in the context, for example, in a listener:

```
<rabbit:listener-container>
    <rabbit:listener ref="listener" queue-names="#{someQueue.name}" />
</rabbit:listener-container>
```

See the section called “Automatic Declaration of Exchanges, Queues and Bindings”.

The RabbitMQ implementation of this interface is RabbitAdmin which when configured using Spring XML would look like this:

```
<rabbit:connection-factory id="connectionFactory"/>

<rabbit:admin id="amqpAdmin" connection-factory="connectionFactory"/>
```

When the `CachingConnectionFactory` cache mode is `CHANNEL` (the default), the `RabbitAdmin` implementation does automatic lazy declaration of `Queues`, `Exchanges` and `Bindings` declared in the same `ApplicationContext`. These components will be declared as son as a `Connection` is opened to the broker. There are some namespace features that make this very convenient, e.g. in the Stocks sample application we have:

```
<rabbit:queue id="tradeQueue"/>

<rabbit:queue id="marketDataQueue"/>

<fanout-exchange name="broadcast.responses"
                 xmlns="http://www.springframework.org/schema/rabbit">
    <bindings>
        <binding queue="tradeQueue"/>
    </bindings>
</fanout-exchange>

<topic-exchange name="app.stock.marketdata"
                xmlns="http://www.springframework.org/schema/rabbit">
    <bindings>
        <binding queue="marketDataQueue" pattern="${stocks.quote.pattern}"/>
    </bindings>
</topic-exchange>
```

In the example above we are using anonymous Queues (actually internally just Queues with names generated by the framework, not by the broker) and refer to them by ID. We can also declare Queues with explicit names, which also serve as identifiers for their bean definitions in the context. E.g.

```
<rabbit:queue name="stocks.trade.queue"/>
```

> **Tip**
>
> You can provide both an **id** and a **name** attribute. This allows you to refer to the queue (for example in a binding) by an id that is independent of the queue name. It also allows standard Spring features such as property placeholders, and SpEL expressions for the queue name; these features are not available when using the name as the bean identifier.

Queues can be configured with additional arguments, for example, *x-message-ttl* or *x-ha-policy*. Using the namespace support, they are provided in the form of a Map of argument name/argument value pairs, using the <rabbit:queue-arguments> element.

```
<rabbit:queue name="withArguments">
    <rabbit:queue-arguments>
        <entry key="x-ha-policy" value="all"/>
    </rabbit:queue-arguments>
</rabbit:queue>
```

By default, the arguments are assumed to be strings. For arguments of other types, the type needs to be provided.

```
<rabbit:queue name="withArguments">
    <rabbit:queue-arguments value-type="java.lang.Long">
        <entry key="x-message-ttl" value="100"/>
    </rabbit:queue-arguments>
</rabbit:queue>
```

When providing arguments of mixed types, the type is provided for each entry element:

```
<rabbit:queue name="withArguments">
    <rabbit:queue-arguments>
        <entry key="x-message-ttl">
            <value type="java.lang.Long">100</value>
        </entry>
        <entry key="x-ha-policy" value="all"/>
    </rabbit:queue-arguments>
</rabbit:queue>
```

With Spring Framework 3.2 and later, this can be declared a little more succinctly:

```
<rabbit:queue name="withArguments">
    <rabbit:queue-arguments>
        <entry key="x-message-ttl" value="100" value-type="java.lang.Long"/>
        <entry key="x-ha-policy" value="all"/>
    </rabbit:queue-arguments>
</rabbit:queue>
```

> **Important**
>
> The RabbitMQ broker will not allow declaration of a queue with mismatched arguments. For example, if a `queue` already exists with no `time to live` argument, and you attempt to declare it with, say, `key="x-message-ttl" value="100"`, an exception will be thrown.

By default, the `RabbitAdmin` will immediately stop processing all declarations when any exception occurs; this could cause downstream issues - such as a **listener container** failing to initialize because another queue (defined after the one in error) is not declared.

This behavior can be modified by setting the `ignore-declaration-failures` attribute to `true` on the `RabbitAdmin`. This option instructs the `RabbitAdmin` to log the exception, and continue declaring other elements.

Starting with *version 1.3* the HeadersExchange can be configured to match on multiple headers; you can also specify whether any or all headers must match:

```
<rabbit:headers-exchange name="headers-test">
 <rabbit:bindings>
  <rabbit:binding queue="bucket">
   <rabbit:binding-arguments>
    <entry key="foo" value="bar"/>
    <entry key="baz" value="qux"/>
    <entry key="x-match" value="all"/>
   </rabbit:binding-arguments>
  </rabbit:binding>
 </rabbit:bindings>
</rabbit:headers-exchange>
```

To see how to use Java to configure the AMQP infrastructure, look at the Stock sample application, where there is the `@Configuration` class `AbstractStockRabbitConfiguration` which in turn has RabbitClientConfiguration and RabbitServerConfiguration subclasses. The code for AbstractStockRabbitConfiguration is shown below

```
@Configuration
public abstract class AbstractStockAppRabbitConfiguration {

    @Bean
    public ConnectionFactory connectionFactory() {
        CachingConnectionFactory connectionFactory =
            new CachingConnectionFactory("localhost");
        connectionFactory.setUsername("guest");
        connectionFactory.setPassword("guest");
        return connectionFactory;
    }

    @Bean
    public RabbitTemplate rabbitTemplate() {
        RabbitTemplate template = new RabbitTemplate(connectionFactory());
        template.setMessageConverter(jsonMessageConverter());
        configureRabbitTemplate(template);
        return template;
    }

    @Bean
    public MessageConverter jsonMessageConverter() {
        return new JsonMessageConverter();
    }

    @Bean
    public TopicExchange marketDataExchange() {
        return new TopicExchange("app.stock.marketdata");
    }

    // additional code omitted for brevity

}
```

In the Stock application, the server is configured using the following @Configuration class:

```
@Configuration
public class RabbitServerConfiguration extends AbstractStockAppRabbitConfiguration  {

    @Bean
    public Queue stockRequestQueue() {
        return new Queue("app.stock.request");
    }
}
```

This is the end of the whole inheritance chain of @Configuration classes. The end result is the the TopicExchange and Queue will be declared to the broker upon application startup. There is no binding of the TopicExchange to a queue in the server configuration, as that is done in the client application.

The stock request queue however is automatically bound to the AMQP default exchange - this behavior is defined by the specification.

The client @Configuration class is a little more interesting and is shown below.

```
@Configuration
public class RabbitClientConfiguration extends AbstractStockAppRabbitConfiguration {

    @Value("${stocks.quote.pattern}")
    private String marketDataRoutingKey;

    @Bean
    public Queue marketDataQueue() {
        return amqpAdmin().declareQueue();
    }

    /**
     * Binds to the market data exchange.
     * Interested in any stock quotes
     * that match its routing key.
     */
    @Bean
    public Binding marketDataBinding() {
        return BindingBuilder.bind(
                marketDataQueue()).to(marketDataExchange()).with(marketDataRoutingKey);
    }

    // additional code omitted for brevity

}
```

The client is declaring another queue via the declareQueue() method on the AmqpAdmin, and it binds that queue to the market data exchange with a routing pattern that is externalized in a properties file.

Declaring Collections of Exchanges, Queues, Bindings

Starting with *version 1.5*, it is now possible to declare multiple entities with one `@Bean`, by returing a collection.

Only collections where the first element is a `Declarable` are considered, and only `Declarable` elements from such collections are processed.

```
@Configuration
public static class Config {

    @Bean
    public ConnectionFactory cf() {
        return new CachingConnectionFactory("localhost");
    }

    @Bean
    public RabbitAdmin admin(ConnectionFactory cf) {
        return new RabbitAdmin(cf);
    }

    @Bean
    public DirectExchange e1() {
     return new DirectExchange("e1", false, true);
    }

    @Bean
    public Queue q1() {
     return new Queue("q1", false, false, true);
    }

    @Bean
    public Binding b1() {
     return BindingBuilder.bind(q1()).to(e1()).with("k1");
    }

    @Bean
    public List<Exchange> es() {
     return Arrays.<Exchange>asList(
       new DirectExchange("e2", false, true),
       new DirectExchange("e3", false, true)
     );
    }

    @Bean
    public List<Queue> qs() {
     return Arrays.asList(
       new Queue("q2", false, false, true),
       new Queue("q3", false, false, true)
     );
    }

    @Bean
    public List<Binding> bs() {
     return Arrays.asList(
       new Binding("q2", DestinationType.QUEUE, "e2", "k2", null),
       new Binding("q3", DestinationType.QUEUE, "e3", "k3", null)
     );
    }

    @Bean
    public List<Declarable> ds() {
     return Arrays.<Declarable>asList(
       new DirectExchange("e4", false, true),
       new Queue("q4", false, false, true),
       new Binding("q4", DestinationType.QUEUE, "e4", "k4", null)
     );
    }

}
```

Conditional Declaration

By default, all queues, exchanges, and bindings are declared by all `RabbitAdmin` instances (that have `auto-startup="true"`) in the application context.

> **Note**
>
> Starting with the 1.2 release, it is possible to conditionally declare these elements. This is particularly useful when an application connects to multiple brokers and needs to specify with which broker(s) a particular element should be declared.

The classes representing these elements implement `Declarable` which has two methods: `shouldDeclare()` and `getDeclaringAdmins()`. The `RabbitAdmin` uses these methods to determine whether a particular instance should actually process the declarations on its `Connection`.

The properties are available as attributes in the namespace, as shown in the following examples.

```
<rabbit:admin id="admin1" connection-factory="CF1" />

<rabbit:admin id="admin2" connection-factory="CF2" />

<rabbit:queue id="declaredByBothAdminsImplicitly" />

<rabbit:queue id="declaredByBothAdmins" declared-by="admin1, admin2" />

<rabbit:queue id="declaredByAdmin1Only" declared-by="admin1" />

<rabbit:queue id="notDeclaredByAny" auto-declare="false" />

<rabbit:direct-exchange name="direct" declared-by="admin1, admin2">
 <rabbit:bindings>
  <rabbit:binding key="foo" queue="bar"/>
 </rabbit:bindings>
</rabbit:direct-exchange>
```

> **Note**
>
> The `auto-declare` attribute is `true` by default and if the `declared-by` is not supplied (or is empty) then all `RabbitAdmin` s will declare the object (as long as the admin's `auto-startup` attribute is true; the default).

Similarly, you can use Java-based `@Configuration` to achieve the same effect. In this example, the components will be declared by `admin1` but not `admin2`:

```
@Bean
public RabbitAdmin admin() {
 RabbitAdmin rabbitAdmin = new RabbitAdmin(cf1());
 rabbitAdmin.afterPropertiesSet();
 return rabbitAdmin;
}

@Bean
public RabbitAdmin admin2() {
 RabbitAdmin rabbitAdmin = new RabbitAdmin(cf2());
 rabbitAdmin.afterPropertiesSet();
 return rabbitAdmin;
}

@Bean
public Queue queue() {
 Queue queue = new Queue("foo");
 queue.setAdminsThatShouldDeclare(admin());
 return queue;
}

@Bean
public Exchange exchange() {
 DirectExchange exchange = new DirectExchange("bar");
 exchange.setAdminsThatShouldDeclare(admin());
 return exchange;
}

@Bean
public Binding binding() {
 Binding binding = new Binding("foo", DestinationType.QUEUE, exchange().getName(), "foo", null);
 binding.setAdminsThatShouldDeclare(admin());
 return binding;
}
```

AnonymousQueue

In general, when needing a uniquely-named, exclusive, auto-delete queue, it is recommended that the `AnonymousQueue` is used instead of broker-defined queue names (using `""` as a `Queue` name will cause the broker to generate the queue name).

This is because:

1. The queues are actually declared when the connection to the broker is established; this is long after the beans are created and wired together; beans using the queue need to know its name. In fact, the broker might not even be running when the app is started.

2. If the connection to the broker is lost for some reason, the admin will re-declare the `AnonymousQueue` with the same name. If we used broker-declared queues, the queue name would change.

Starting with *version 1.5.3*, you can control the format of the queue name used by `AnonymousQueue` s.

By default, the queue name is the String representation of a `UUID`; for example: `07afcfe9-fe77-4983-8645-0061ec61a47a`.

You can now provide an `AnonymousQueue.NamingStrategy` implementation in a constructor argument:

```
@Bean
public Queue anon1() {
    return new AnonymousQueue(new AnonymousQueue.Base64UrlNamingStrategy());
}

@Bean
public Queue anon2() {
    return new AnonymousQueue(new AnonymousQueue.Base64UrlNamingStrategy("foo-"));
}
```

The first will generate a queue name prefixed by `spring.gen-` followed by a base64 representation of the `UUID`, for example: `spring.gen-MRBv9sqISkuCiPfOYfpo4g`. The second will generate a queue name prefixed by `foo-` followed by a base64 representation of the `UUID`.

The base64 encoding uses the "URL and Filename Safe Alphabet" from RFC 4648; trailing padding characters (=) are removed.

You can provide your own naming strategy, whereby you can include other information (e.g. application, client host) in the queue name.

RabbitMQ REST API

When the management plugin is enabled, the RabbitMQ server exposes a REST API to monitor and configure the broker. A Java Binding for the API is now provided. In general, you can use that API directly, but a convenience wrapper is provided to use the familiar Spring AMQP `Queue`, `Exchange`, and `Binding` domain objects with the API. Much more information is available for these objects when using the `com.rabbitmq.http.client.Client` API directly (`QueueInfo`, `ExchangeInfo`, and `BindingInfo` respectively). The following operations are available on the `RabbitManagementTemplate`:

```
public interface AmqpManagementOperations {

 void addExchange(Exchange exchange);

 void addExchange(String vhost, Exchange exchange);

 void purgeQueue(Queue queue);

 void purgeQueue(String vhost, Queue queue);

 void deleteQueue(Queue queue);

 void deleteQueue(String vhost, Queue queue);

 Queue getQueue(String name);

 Queue getQueue(String vhost, String name);

 List<Queue> getQueues();

 List<Queue> getQueues(String vhost);

 void addQueue(Queue queue);

 void addQueue(String vhost, Queue queue);

 void deleteExchange(Exchange exchange);

 void deleteExchange(String vhost, Exchange exchange);

 Exchange getExchange(String name);

 Exchange getExchange(String vhost, String name);

 List<Exchange> getExchanges();

 List<Exchange> getExchanges(String vhost);

 List<Binding> getBindings();

 List<Binding> getBindings(String vhost);

 List<Binding> getBindingsForExchange(String vhost, String exchange);

}
```

Refer to the javadocs for more information.

Exception Handling

Many operations with the RabbitMQ Java client can throw checked Exceptions. For example, there are a lot of cases where IOExceptions may be thrown. The RabbitTemplate, SimpleMessageListenerContainer, and other Spring AMQP components will catch those Exceptions and convert into one of the Exceptions within our runtime hierarchy. Those are defined in the *org.springframework.amqp* package, and AmqpException is the base of the hierarchy.

When a listener throws an exception, it is wrapped in a `ListenerExecutionFailedException` and, normally the message is rejected and requeued by the broker. Setting `defaultRequeueRejected` to false will cause messages to be discarded (or routed to a dead letter exchange). As discussed in the section called “Message Listeners and the Asynchronous Case”, the listener can throw an `AmqpRejectAndDontRequeueException` to conditionally control this behavior.

However, there is a class of errors where the listener cannot control the behavior. When a message that cannot be converted is encountered (for example an invalid `content_encoding` header),

the `MessageConversionException` is thrown before the message reaches user code. With `defaultRequeueRejected` set to `true` (default), such messages would be redelivered over and over. Before *version 1.3.2*, users needed to write a custom `ErrorHandler`, as discussed in the section called “Exception Handling” to avoid this situation.

Starting with *version 1.3.2*, the default `ErrorHandler` is now a `ConditionalRejectingErrorHandler` which will reject (and not requeue) messages that fail with a `MessageConversionException`. An instance of this error handler can be configured with a `FatalExceptionStrategy` so users can provide their own rules for conditional message rejection, e.g. a delegate implementation to the `BinaryExceptionClassifier` from Spring Retry (the section called “Message Listeners and the Asynchronous Case”). In addition, the `ListenerExecutionFailedException` now has a `failedMessage` property which can be used in the decision. If the `FatalExceptionStrategy.isFatal()` method returns `true`, the error handler throws an `AmqpRejectAndDontRequeueException`. The default `FatalExceptionStrategy` logs a warning message.

Transactions

Introduction

The Spring Rabbit framework has support for automatic transaction management in the synchronous and asynchronous use cases with a number of different semantics that can be selected declaratively, as is familiar to existing users of Spring transactions. This makes many if not most common messaging patterns very easy to implement.

There are two ways to signal the desired transaction semantics to the framework. In both the `RabbitTemplate` and `SimpleMessageListenerContainer` there is a flag `channelTransacted` which, if true, tells the framework to use a transactional channel and to end all operations (send or receive) with a commit or rollback depending on the outcome, with an exception signaling a rollback. Another signal is to provide an external transaction with one of Spring’s `PlatformTransactionManager` implementations as a context for the ongoing operation. If there is already a transaction in progress when the framework is sending or receiving a message, and the `channelTransacted` flag is true, then the commit or rollback of the messaging transaction will be deferred until the end of the current transaction. If the `channelTransacted` flag is false, then no transaction semantics apply to the messaging operation (it is auto-acked).

The `channelTransacted` flag is a configuration time setting: it is declared and processed once when the AMQP components are created, usually at application startup. The external transaction is more dynamic in principle because the system responds to the current Thread state at runtime, but in practice is often also a configuration setting, when the transactions are layered onto an application declaratively.

For synchronous use cases with `RabbitTemplate` the external transaction is provided by the caller, either declaratively or imperatively according to taste (the usual Spring transaction model). An example of a declarative approach (usually preferred because it is non-invasive), where the template has been configured with `channelTransacted=true`:

```
@Transactional
public void doSomething() {
    String incoming = rabbitTemplate.receiveAndConvert();
    // do some more database processing...
    String outgoing = processInDatabaseAndExtractReply(incoming);
    rabbitTemplate.convertAndSend(outgoing);
}
```

A String payload is received, converted and sent as a message body inside a method marked as @Transactional, so if the database processing fails with an exception, the incoming message will be returned to the broker, and the outgoing message will not be sent. This applies to any operations with the `RabbitTemplate` inside a chain of transactional methods (unless the `Channel` is directly manipulated to commit the transaction early for instance).

For asynchronous use cases with `SimpleMessageListenerContainer` if an external transaction is needed it has to be requested by the container when it sets up the listener. To signal that an external transaction is required the user provides an implementation of `PlatformTransactionManager` to the container when it is configured. For example:

```
@Configuration
public class ExampleExternalTransactionAmqpConfiguration {

    @Bean
    public SimpleMessageListenerContainer messageListenerContainer() {
        SimpleMessageListenerContainer container = new SimpleMessageListenerContainer();
        container.setConnectionFactory(rabbitConnectionFactory());
        container.setTransactionManager(transactionManager());
        container.setChannelTransacted(true);
        container.setQueueName("some.queue");
        container.setMessageListener(exampleListener());
        return container;
    }

}
```

In the example above, the transaction manager is added as a dependency injected from another bean definition (not shown), and the `channelTransacted` flag is also set to true. The effect is that if the listener fails with an exception the transaction will be rolled back, and the message will also be returned to the broker. Significantly, if the transaction fails to commit (e.g. a database constraint error, or connectivity problem), then the AMQP transaction will also be rolled back, and the message will be returned to the broker. This is sometimes known as a Best Efforts 1 Phase Commit, and is a very powerful pattern for reliable messaging. If the `channelTransacted` flag was set to false in the example above, which is the default, then the external transaction would still be provided for the listener, but all messaging operations would be auto-acked, so the effect is to commit the messaging operations even on a rollback of the business operation.

A note on Rollback of Received Messages

AMQP transactions only apply to messages and acks sent to the broker, so when there is a rollback of a Spring transaction and a message has been received, what Spring AMQP has to do is not just rollback the transaction, but also manually reject the message (sort of a nack, but that's not what the specification calls it). The action taken on message rejection is independent of transactions and depends on the `defaultRequeueRejected` property (default `true`). For more information about rejecting failed messages, see the section called "Message Listeners and the Asynchronous Case".

For more information about RabbitMQ transactions, and their limitations, refer to RabbitMQ Broker Semantics.

> **Note**
>
> Prior to **RabbitMQ 2.7.0**, such messages (and any that are unacked when a channel is closed or aborts) went to the back of the queue on a Rabbit broker, since 2.7.0, rejected messages go to the front of the queue, in a similar manner to JMS rolled back messages.

Using the RabbitTransactionManager

The RabbitTransactionManager is an alternative to executing Rabbit operations within, and synchronized with, external transactions. This Transaction Manager is an implementation of the PlatformTransactionManager interface and should be used with a single Rabbit ConnectionFactory.

> **Important**
>
> This strategy is not able to provide XA transactions, for example in order to share transactions between messaging and database access.

Application code is required to retrieve the transactional Rabbit resources via `ConnectionFactoryUtils.getTransactionalResourceHolder(ConnectionFactory, boolean)` instead of a standard `Connection.createChannel()` call with subsequent Channel creation. When using Spring AMQP's RabbitTemplate, it will autodetect a thread-bound Channel and automatically participate in its transaction.

With Java Configuration you can setup a new RabbitTransactionManager using:

```
@Bean
public RabbitTransactionManager rabbitTransactionManager() {
    return new RabbitTransactionManager(connectionFactory);
}
```

If you prefer using XML configuration, declare the following bean in your XML Application Context file:

```
<bean id="rabbitTxManager"
      class="org.springframework.amqp.rabbit.transaction.RabbitTransactionManager">
    <property name="connectionFactory" ref="connectionFactory"/>
</bean>
```

Message Listener Container Configuration

There are quite a few options for configuring a `SimpleMessageListenerContainer` related to transactions and quality of service, and some of them interact with each other.

The table below shows the container property names and their equivalent attribute names (in parentheses) when using the namespace to configure a `<rabbit:listener-container/>`.

Some properties are not exposed by the namespace; indicated by `N/A`for the attribute.

Table 3.1. Configuration options for a message listener container

Property (Attribute)	Description
`(group)`	This is only available when using the namespace. When specified, a bean of type `Collection<MessageListenerContainer>` is registered with this name, and the container for each `<listener/>` element is added to the collection. This allows, for example, starting/stopping the group of containers by iterating over the collection. If multiple `<listener-container/>` elements have the same group value, the containers in the collection is an aggregate of all containers so designated.
`channelTransacted (channel-transacted)`	Boolean flag to signal that all messages should be acknowledged in a transaction (either manually or automatically)

Property (Attribute)	Description
acknowledgeMode (acknowledge)	• NONE = no acks will be sent (incompatible with channelTransacted=true). RabbitMQ calls this "autoack" because the broker assumes all messages are acked without any action from the consumer. • MANUAL = the listener must acknowledge all messages by calling Channel.basicAck(). • AUTO = the container will acknowledge the message automatically, unless the MessageListener throws an exception. Note that acknowledgeMode is complementary to channelTransacted - if the channel is transacted then the broker requires a commit notification in addition to the ack. This is the default mode. See also txSize.
transactionManager (transaction-manager)	External transaction manager for the operation of the listener. Also complementary to channelTransacted - if the Channel is transacted then its transaction will be synchronized with the external transaction.
prefetchCount (prefetch)	The number of messages to accept from the broker in one socket frame. The higher this is the faster the messages can be delivered, but the higher the risk of non-sequential processing. Ignored if the acknowledgeMode is NONE. This will be increased, if necessary, to match the txSize.
shutdownTimeout (N/A)	When a container shuts down (e.g. if its enclosing ApplicationContext is closed) it waits for in-flight messages to be processed up to this limit. Defaults to 5 seconds. After the limit is reached, if the channel is not transacted messages will be discarded.
txSize (transaction-size)	When used with acknowledgeMode AUTO, the container will attempt to process up to this number of messages before sending an ack (waiting for each one up to the receive timeout setting). This is also when a transactional channel is committed. If the prefetchCount is less than the txSize, it will be increased to match the txSize.
receiveTimeout (receive-timeout)	The maximum time to wait for each message. If acknowledgeMode=NONE this has very little effect - the container just spins round and asks for another message. It has the biggest effect for a transactional Channel with txSize > 1, since it can cause messages already consumed not to be acknowledged until the timeout expires.
autoStartup (auto-startup)	Flag to indicate that the container should start when the ApplicationContext does (as part of the SmartLifecycle callbacks which happen after all beans are initialized). Defaults to true, but set it to false if your broker might not be available on

Property (Attribute)	Description
	startup, and then call `start()` later manually when you know the broker is ready.
`phase` (`phase`)	When autoStartup is true, the lifecycle phase within which this container should start and stop. The lower the value the earlier this container will start and the later it will stop. The default is Integer.MAX_VALUE meaning the container will start as late as possible and stop as soon as possible.
`adviceChain` (`advice-chain`)	An array of AOP Advice to apply to the listener execution. This can be used to apply additional cross cutting concerns such as automatic retry in the event of broker death. Note that simple re-connection after an AMQP error is handled by the `CachingConnectionFactory`, as long as the broker is still alive.
`taskExecutor` (`task-executor`)	A reference to a Spring TaskExecutor (or standard JDK 1.5+ Executor) for executing listener invokers. Default is a SimpleAsyncTaskExecutor, using internally managed threads.
`errorHandler` (`error-handler`)	A reference to an ErrorHandler strategy for handling any uncaught Exceptions that may occur during the execution of the MessageListener. Default: `ConditionalRejectingErrorHandler`
`concurrentConsumers` (`concurrency`)	The number of concurrent consumers to initially start for each listener. See the section called “Listener Concurrency”.
`maxConcurrentConsumers` (`max-concurrency`)	The maximum number of concurrent consumers to start, if needed, on demand. Must be greater than or equal to *concurrentConsumers*. See the section called “Listener Concurrency”.
`startConsumerMinInterval` (`min-start-interval`)	The time in milliseconds which must elapse before each new consumer is started on demand. See the section called “Listener Concurrency”. Default 10000 (10 seconds).
`stopConsumerMinInterval` (`min-stop-interval`)	The time in milliseconds which must elapse before a consumer is stopped, since the last consumer was stopped, when an idle consumer is detected. See the section called “Listener Concurrency”. Default 60000 (1 minute).
`consecutiveActiveTrigger` (`min-consecutive-active`)	The minimum number of consecutive messages received by a consumer, without a receive timeout occurring, when considering starting a new consumer. Also impacted by *txSize*. See the section called “Listener Concurrency”. Default 10.
`consecutiveIdleTrigger` (`min-consecutive-idle`)	The minimum number of receive timeouts a consumer must experience before considering stopping a consumer. Also impacted by *txSize*. See the section called “Listener Concurrency”. Default 10.

Property (Attribute)	Description
`connectionFactory` (`connection-factory`)	A reference to the connectionFactory; when configuring using the XML namespace, the default referenced bean name is "rabbitConnectionFactory".
`defaultRequeueRejected` (`requeue-rejected`)	Determines whether messages that are rejected because the listener threw an exception should be requeued or not. Default *true*.
`recoveryInterval` (`recovery-interval`)	Determines the time in milliseconds between attempts to start a consumer if it fails to start for non-fatal reasons. Default *5000*. Mutually exclusive with `recoveryBackOff`.
`recoveryBackOff` (`recovery-back-off`)	Specifies the `BackOff` for intervals between attempts to start a consumer if it fails to start for non-fatal reasons. Default is `FixedBackOff` with unlimited retries every 5 seconds. Mutually exclusive with `recoveryInterval`.
`exclusive` (`exclusive`)	Determines whether the single consumer in this container has exclusive access to the queue(s). The concurrency of the container must be 1 when this is true. If another consumer has exclusive access, the container will attempt to recover the consumer, according to the `recovery-interval` or `recovery-back-off`. When using the namespace, this attribute appears on the <rabbit:listener/> element along with the queue names. Default *false*.
`rabbitAdmin` (`admin`)	When a listener container listens to at least one auto-delete queue and it is found to be missing during startup, the container uses a `RabbitAdmin` to declare the queue and any related bindings and exchanges. If such elements are configured to use conditional declaration (see the section called “Conditional Declaration”), the container must use the admin that was configured to declare those elements. Specify that admin here; only required when using auto-delete queues with conditional declaration. If you do not wish the auto-delete queue(s) to be declared until the container is started, set `auto-startup` to `false` on the admin. Defaults to a `RabbitAdmin` that will declare all non-conditional elements.
`missingQueuesFatal` (`missing-queues-fatal`)	Starting with *version 1.3.5*, `SimpleMessageListenerContainer` has this new property. When set to `true` (default), if none of the configured queues are available on the broker, it is considered fatal. This causes the application context to fail to initialize during startup; also, when the queues are deleted while the container is running, by default, the consumers make 3 retries to connect to the queues (at 5 second intervals) and stop the container if these attempts fail. This was not configurable in previous versions.

Property (Attribute)	Description

	When set to `false`, after making the 3 retries, the container will go into recovery mode, as with other problems, such as the broker being down. The container will attempt to recover according to the `recoveryInterval` property. During each recovery attempt, each consumer will again try 4 times to passively declare the queues at 5 second intervals. This process will continue indefinitely.
	
	You can also use a properties bean to set the property globally for all containers, as follows:
	
	`<util:properties id="spring.amqp.global.properties">`
	`  <prop key="smlc.missing.queues.fatal">false</prop>`
	`</util:properties>`
	
	This global property will not be applied to any containers that have an explicit `missingQueuesFatal` property set.
	
	The default retry properties (3 retries at 5 second intervals) can be overridden using the properties below.

`autoDeclare (auto-declare)`	Starting with *version 1.4*, `SimpleMessageListenerContainer` has this new property. When set to `true` (default), the container will redeclare all AMQP objects (Queues, Exchanges, Bindings), if it detects that at least one of its queues is missing during startup, perhaps because it's an `auto-delete` or an expired queue, but the redeclaration will proceed if the queue is missing for any reason. To disable this behavior, set this property to `false`. Note that the container will fail to start if all of its queues are missing.
`declarationRetries (declaration-retries)`	Starting with *versions 1.4.3, 1.3.9*, `SimpleMessageListenerContainer` has this new property. The namespace attribute is available in *version 1.5.x* The number of retry attempts when passive queue declaration fails. Passive queue declaration occurs when the consumer starts or, when consuming from multiple queues, when not all queues were available during initialization. When none of the configured queues can be passively declared (for any reason) after the retries are exhausted, the container behavior is controlled by the 'missingQueuesFatal` property above. Default: 3 retries (4 attempts).
`failedDeclarationRetryInterval (failed-declaration-retry-interval)`	Starting with *versions 1.4.3, 1.3.9*, `SimpleMessageListenerContainer` has this new property. The namespace attribute is available in *version 1.5.x* The interval between passive queue declaration retry attempts. Passive queue declaration occurs when the consumer starts or,

Property (Attribute)	Description
	when consuming from multiple queues, when not all queues were available during initialization. Default: 5000 (5 seconds).
`retryDeclarationInterval (missing-queue-retry-interval)`	Starting with *versions 1.4.3, 1.3.9*, `SimpleMessageListenerContainer` has this new property. The namespace attribute is available in *version 1.5.x* If a subset of the configured queues are available during consumer initialization, the consumer starts consuming from those queues. The consumer will attempt to passively declare the missing queues using this interval. When this interval elapses, the *declarationRetries* and *failedDeclarationRetryInterval* will again be used. If there are still missing queues, the consumer will again wait for this interval before trying again. This process will continue indefinitely until all queues are available. Default: 60000 (1 minute).
`consumerTagStrategy (consumer-tag-strategy)`	Starting with *version 1.4.5*, `SimpleMessageListenerContainer` has this new property. The namespace attribute is available in *version 1.5.x* Previously, only broker-generated consumer tags can be used; while this is still the default, you can now provide an implementation of ConsumerTagStrategy, enabling the creation of a (unique) tag for each consumer.

Listener Concurrency

By default, the listener container will start a single consumer which will receive messages from the queue(s).

When examining the table in the previous section, you will see a number of properties/attributes that control concurrency. The simplest is `concurrentConsumers`, which simply creates that (fixed) number of consumers which will concurrently process messages.

Prior to *version 1.3.0*, this was the only setting available and the container had to be stopped and started again to change the setting.

Since *version 1.3.0*, you can now dynamically adjust the `concurrentConsumers` property. If it is changed while the container is running, consumers will be added or removed as necessary to adjust to the new setting.

In addition, a new property `maxConcurrentConsumers` has been added and the container will dynamically adjust the concurrency based on workload. This works in conjunction with four additional properties: `consecutiveActiveTrigger`, `startConsumerMinInterval`, `consecutiveIdleTrigger`, `stopConsumerMinInterval`. With the default settings, the algorithm to increase consumers works as follows:

If the `maxConcurrentConsumers` has not been reached and an existing consumer is active for 10 consecutive cycles AND at least 10 seconds has elapsed since the last consumer was started, a new consumer is started. A consumer is considered active if it received at least one message in `txSize` * `receiveTimeout` milliseconds.

With the default settings, the algorithm to decrease consumers works as follows:

If there are more than `concurrentConsumers` running and a consumer detects 10 consecutive timeouts (idle) AND the last consumer was stopped at least 60 seconds ago, a consumer will be stopped. The timeout depends on the `receiveTimeout` and the `txSize` properties. A consumer is considered idle if it receives no messages in `txSize` * `receiveTimeout` milliseconds. So, with the default timeout (1 second) and a `txSize` of 4, stopping a consumer will be considered after 40 seconds of idle time (4 timeouts correspond to 1 idle detection).

> **Note**
>
> Practically, consumers will only be stopped if the whole container is idle for some time. This is because the broker will share its work across all the active consumers.

Exclusive Consumer

Also starting with *version 1.3*, the listener container can be configured with a single exclusive consumer; this prevents other containers from consuming from the queue(s) until the current consumer is cancelled. The concurrency of such a container must be 1.

When using exclusive consumers, other containers will attempt to consume from the queue(s) according to the `recoveryInterval` property, and log a WARNing if the attempt fails.

Listener Container Queues

version 1.3 introduced a number of improvements for handling multiple queues in a listener container.

The container must be configured to listen on at least one queue; this was the case previously too, but now queues can be added and removed at runtime. The container will recycle (cancel and re-create) the consumers when any pre-fetched messages have been processed. See methods `addQueues`, `addQueueNames`, `removeQueues` and `removeQueueNames`. When removing queues, at least one queue must remain.

A consumer will now start if any of its queues are available - previously the container would stop if any queues were unavailable. Now, this is only the case if none of the queues are available. If not all queues are available, the container will attempt to passively declare (and consume from) the missing queue(s) every 60 seconds.

Also, if a consumer receives a cancel from the broker (for example if a queue is deleted) the consumer will attempt to recover and the recovered consumer will continue to process messages from any other configured queues. Previously a cancel on one queue cancelled the entire consumer and eventually the container would stop due to the missing queue.

If you wish to permanently remove a queue, you should update the container before or after deleting to queue, to avoid future attempts to consume from it.

Resilience: Recovering from Errors and Broker Failures

Introduction

Some of the key (and most popular) high-level features that Spring AMQP provides are to do with recovery and automatic re-connection in the event of a protocol error or broker failure. We have seen all the relevant components already in this guide, but it should help to bring them all together here and call out the features and recovery scenarios individually.

The primary reconnection features are enabled by the `CachingConnectionFactory` itself. It is also often beneficial to use the `RabbitAdmin` auto-declaration features. In addition, if you care about guaranteed delivery, you probably also need to use the `channelTransacted` flag in `RabbitTemplate` and `SimpleMessageListenerContainer` and also the `AcknowledgeMode.AUTO` (or manual if you do the acks yourself) in the `SimpleMessageListenerContainer`.

Automatic Declaration of Exchanges, Queues and Bindings

The `RabbitAdmin` component can declare exchanges, queues and bindings on startup. It does this lazily, through a `ConnectionListener`, so if the broker is not present on startup it doesn't matter. The first time a `Connection` is used (e.g. by sending a message) the listener will fire and the admin features will be applied. A further benefit of doing the auto declarations in a listener is that if the connection is dropped for any reason (e.g. broker death, network glitch, etc.) they will be applied again the next time they are needed.

> **Note**
>
> Queues declared this way must have fixed names; either explicitly declared, or generated by the framework for `AnonymousQueue` s. Anonymous queues are non-durable, exclusive, and auto-delete.

> **Important**
>
> Automatic declaration is only performed when the `CachingConnectionFactory` cache mode is `CHANNEL` (the default). This limitation exists because exlusive and auto-delete queues are bound to the connection.

Failures in Synchronous Operations and Options for Retry

If you lose your connection to the broker in a synchronous sequence using `RabbitTemplate` (for instance), then Spring AMQP will throw an `AmqpException` (usually but not always `AmqpIOException`). We don't try to hide the fact that there was a problem, so you have to be able to catch and respond to the exception. The easiest thing to do if you suspect that the connection was lost, and it wasn't your fault, is to simply try the operation again. You can do this manually, or you could look at using Spring Retry to handle the retry (imperatively or declaratively).

Spring Retry provides a couple of AOP interceptors and a great deal of flexibility to specify the parameters of the retry (number of attempts, exception types, backoff algorithm etc.). Spring AMQP also provides some convenience factory beans for creating Spring Retry interceptors in a convenient form for AMQP use cases, with strongly typed callback interfaces for you to implement custom recovery logic. See the Javadocs and properties of `StatefulRetryOperationsInterceptor` and `StatelessRetryOperationsInterceptor` for more detail. Stateless retry is appropriate if there is no transaction or if a transaction is started inside the retry callback. Note that stateless retry is simpler to configure and analyse than stateful retry, but it is not usually appropriate if there is an ongoing transaction which must be rolled back or definitely is going to roll back. A dropped connection in the middle of a transaction should have the same effect as a rollback, so for reconnection where the transaction is started higher up the stack, stateful retry is usually the best choice.

Starting with *version 1.3*, a builder API is provided to aid in assembling these interceptors using Java (or in `@Configuration` classes), for example:

```
@Bean
public StatefulRetryOperationsInterceptor interceptor() {
 return RetryInterceptorBuilder.stateful()
   .maxAttempts(5)
   .backOffOptions(1000, 2.0, 10000) // initialInterval, multiplier, maxInterval
   .build();
}
```

Only a subset of retry capabilities can be configured this way; more advanced features would need the configuration of a `RetryTemplate` as a Spring bean. See the Spring Retry Javadocs for complete information about available policies and their configuration.

Message Listeners and the Asynchronous Case

If a `MessageListener` fails because of a business exception, the exception is handled by the message listener container and then it goes back to listening for another message. If the failure is caused by a dropped connection (not a business exception), then the consumer that is collecting messages for the listener has to be cancelled and restarted. The `SimpleMessageListenerContainer` handles this seamlessly, and it leaves a log to say that the listener is being restarted. In fact it loops endlessly trying to restart the consumer, and only if the consumer is very badly behaved indeed will it give up. One side effect is that if the broker is down when the container starts, it will just keep trying until a connection can be established.

Business exception handling, as opposed to protocol errors and dropped connections, might need more thought and some custom configuration, especially if transactions and/or container acks are in use. Prior to 2.8.x, RabbitMQ had no definition of dead letter behaviour, so by default a message that is rejected or rolled back because of a business exception can be redelivered ad infinitum. To put a limit in the client on the number of re-deliveries, one choice is a `StatefulRetryOperationsInterceptor` in the advice chain of the listener. The interceptor can have a recovery callback that implements a custom dead letter action: whatever is appropriate for your particular environment.

Another alternative is to set the container's rejectRequeued property to false. This causes all failed messages to be discarded. When using RabbitMQ 2.8.x or higher, this also facilitates delivering the message to a Dead Letter Exchange.

Or, you can throw a `AmqpRejectAndDontRequeueException`; this prevents message requeuing, regardless of the setting of the `defaultRequeueRejected` property.

Often, a combination of both techniques will be used. Use a `StatefulRetryOperationsInterceptor` in the advice chain, where it's `MessageRecover` throws an `AmqpRejectAndDontRequeueException`. The `MessageRecover` is called when all retries have been exhausted. The default `MessageRecoverer` simply consumes the errant message and emits a WARN message. In which case, the message is ACK'd and won't be sent to the Dead Letter Exchange, if any.

Starting with *version 1.3*, a new `RepublishMessageRecoverer` is provided, to allow publishing of failed messages after retries are exhausted:

```
@Bean
RetryOperationsInterceptor interceptor() {
 return RetryInterceptorBuilder.stateless()
   .maxAttempts(5)
   .recoverer(new RepublishMessageRecoverer(amqpTemplate(), "bar", "baz"))
   .build();
}
```

The `RepublishMessageRecoverer` publishes the message with additional information in message headers, such as the exception message, stack trace, original exchange and routing key. Additional headers can be added by creating a subclass and overriding `additionalHeaders()`.

Exception Classification for Retry

Spring Retry has a great deal of flexibility for determining which exceptions can invoke retry. The default configuration will retry for all exceptions. Given that user exceptions will be wrapped in a `ListenerExecutionFailedException` we need to ensure that the classification examines the exception causes. The default classifier just looks at the top level exception.

Since **Spring Retry 1.0.3**, the `BinaryExceptionClassifier` has a property `traverseCauses` (default `false`). When `true` it will traverse exception causes until it finds a match or there is no cause.

To use this classifier for retry, use a `SimpleRetryPolicy` created with the constructor that takes the max attempts, the `Map` of `Exception` s and the boolean (traverseCauses), and inject this policy into the `RetryTemplate`.

Debugging

Spring AMQP provides extensive logging, especially at `DEBUG` level.

If you wish to monitor the AMQP protocol between the application and broker, you could use a tool such as WireShark, which has a plugin to decode the protocol. Alternatively the RabbitMQ java client comes with a very useful class `Tracer`. When run as a `main`, by default, it listens on port 5673 and connects to port 5672 on localhost. Simply run it, and change your connection factory configuration to connect to port 5673 on localhost. It displays the decoded protocol on the console. Refer to the `Tracer` javadocs for more information.

3.2 Sample Applications

Introduction

The Spring AMQP Samples project includes two sample applications. The first is a simple "Hello World" example that demonstrates both synchronous and asynchronous message reception. It provides an excellent starting point for acquiring an understanding of the essential components. The second sample is based on a stock-trading use case to demonstrate the types of interaction that would be common in real world applications. In this chapter, we will provide a quick walk-through of each sample so that you can focus on the most important components. The samples are both Maven-based, so you should be able to import them directly into any Maven-aware IDE (such as SpringSource Tool Suite).

Hello World

Introduction

The Hello World sample demonstrates both synchronous and asynchronous message reception. You can import the *spring-rabbit-helloworld* sample into the IDE and then follow the discussion below.

Synchronous Example

Within the *src/main/java* directory, navigate to the *org.springframework.amqp.helloworld* package. Open the HelloWorldConfiguration class and notice that it contains the @Configuration annotation at class-level and some @Bean annotations at method-level. This is an example of Spring's Java-based configuration. You can read more about that here.

```
@Bean
public ConnectionFactory connectionFactory() {
    CachingConnectionFactory connectionFactory =
        new CachingConnectionFactory("localhost");
    connectionFactory.setUsername("guest");
    connectionFactory.setPassword("guest");
    return connectionFactory;
}
```

The configuration also contains an instance of `RabbitAdmin`, which by default looks for any beans of type Exchange, Queue, or Binding and then declares them on the broker. In fact, the "helloWorldQueue" bean that is generated in HelloWorldConfiguration is an example simply because it is an instance of Queue.

```
@Bean
public Queue helloWorldQueue() {
    return new Queue(this.helloWorldQueueName);
}
```

Looking back at the "rabbitTemplate" bean configuration, you will see that it has the helloWorldQueue's name set as its "queue" property (for receiving Messages) and for its "routingKey" property (for sending Messages).

Now that we've explored the configuration, let's look at the code that actually uses these components. First, open the Producer class from within the same package. It contains a main() method where the Spring ApplicationContext is created.

```
public static void main(String[] args) {
    ApplicationContext context =
        new AnnotationConfigApplicationContext(RabbitConfiguration.class);
    AmqpTemplate amqpTemplate = context.getBean(AmqpTemplate.class);
    amqpTemplate.convertAndSend("Hello World");
    System.out.println("Sent: Hello World");
}
```

As you can see in the example above, the AmqpTemplate bean is retrieved and used for sending a Message. Since the client code should rely on interfaces whenever possible, the type is AmqpTemplate rather than RabbitTemplate. Even though the bean created in HelloWorldConfiguration is an instance of RabbitTemplate, relying on the interface means that this code is more portable (the configuration can be changed independently of the code). Since the convertAndSend() method is invoked, the template will be delegating to its MessageConverter instance. In this case, it's using the default SimpleMessageConverter, but a different implementation could be provided to the "rabbitTemplate" bean as defined in HelloWorldConfiguration.

Now open the Consumer class. It actually shares the same configuration base class which means it will be sharing the "rabbitTemplate" bean. That's why we configured that template with both a "routingKey" (for sending) and "queue" (for receiving). As you saw in the section called "AmqpTemplate", you could instead pass the *routingKey* argument to the send method and the *queue* argument to the receive method. The Consumer code is basically a mirror image of the Producer, calling receiveAndConvert() rather than convertAndSend().

```
public static void main(String[] args) {
    ApplicationContext context =
        new AnnotationConfigApplicationContext(RabbitConfiguration.class);
    AmqpTemplate amqpTemplate = context.getBean(AmqpTemplate.class);
    System.out.println("Received: " + amqpTemplate.receiveAndConvert());
}
```

If you run the Producer, and then run the Consumer, you should see the message "Received: Hello World" in the console output.

Asynchronous Example

Now that we've walked through the synchronous Hello World sample, it's time to move on to a slightly more advanced but significantly more powerful option. With a few modifications, the Hello World sample can provide an example of asynchronous reception, a.k.a. **Message-driven POJOs**. In fact, there is a sub-package that provides exactly that: org.springframework.amqp.samples.helloworld.async.

Once again, we will start with the sending side. Open the ProducerConfiguration class and notice that it creates a "connectionFactory" and "rabbitTemplate" bean. This time, since the configuration is dedicated to the message sending side, we don't even need any Queue definitions, and the RabbitTemplate only has the *routingKey* property set. Recall that messages are sent to an Exchange rather than being sent directly to a Queue. The AMQP default Exchange is a direct Exchange with no name. All Queues are bound to that default Exchange with their name as the routing key. That is why we only need to provide the routing key here.

```
public RabbitTemplate rabbitTemplate() {
    RabbitTemplate template = new RabbitTemplate(connectionFactory());
    template.setRoutingKey(this.helloWorldQueueName);
    return template;
}
```

Since this sample will be demonstrating asynchronous message reception, the producing side is designed to continuously send messages (if it were a message-per-execution model like the synchronous version, it would not be quite so obvious that it is in fact a message-driven consumer). The component responsible for sending messages continuously is defined as an inner class within the ProducerConfiguration. It is configured to execute every 3 seconds.

```
static class ScheduledProducer {

    @Autowired
    private volatile RabbitTemplate rabbitTemplate;

    private final AtomicInteger counter = new AtomicInteger();

    @Scheduled(fixedRate = 3000)
    public void sendMessage() {
        rabbitTemplate.convertAndSend("Hello World " + counter.incrementAndGet());
    }
}
```

You don't need to understand all of the details since the real focus should be on the receiving side (which we will cover momentarily). However, if you are not yet familiar with Spring 3.0 task scheduling support, you can learn more here. The short story is that the "postProcessor" bean in the ProducerConfiguration is registering the task with a scheduler.

Now, let's turn to the receiving side. To emphasize the Message-driven POJO behavior will start with the component that is reacting to the messages. The class is called HelloWorldHandler.

```
public class HelloWorldHandler {

    public void handleMessage(String text) {
        System.out.println("Received: " + text);
    }

}
```

Clearly, that **is** a POJO. It does not extend any base class, it doesn't implement any interfaces, and it doesn't even contain any imports. It is being "adapted" to the MessageListener interface by the Spring AMQP MessageListenerAdapter. That adapter can then be configured on a SimpleMessageListenerContainer. For this sample, the container is created in the ConsumerConfiguration class. You can see the POJO wrapped in the adapter there.

```
@Bean
public SimpleMessageListenerContainer listenerContainer() {
    SimpleMessageListenerContainer container = new SimpleMessageListenerContainer();
    container.setConnectionFactory(connectionFactory());
    container.setQueueName(this.helloWorldQueueName);
    container.setMessageListener(new MessageListenerAdapter(new HelloWorldHandler()));
    return container;
}
```

The SimpleMessageListenerContainer is a Spring lifecycle component and will start automatically by default. If you look in the Consumer class, you will see that its main() method consists of nothing more than a one-line bootstrap to create the ApplicationContext. The Producer's main() method is also a one-line bootstrap, since the component whose method is annotated with @Scheduled will also start executing automatically. You can start the Producer and Consumer in any order, and you should see messages being sent and received every 3 seconds.

Stock Trading

The Stock Trading sample demonstrates more advanced messaging scenarios than the Hello World sample. However, the configuration is very similar - just a bit more involved. Since we've walked through the Hello World configuration in detail, here we'll focus on what makes this sample different. There is a server that pushes market data (stock quotes) to a Topic Exchange. Then, clients can subscribe to the market data feed by binding a Queue with a routing pattern (e.g. "app.stock.quotes.nasdaq.*"). The other main feature of this demo is a request-reply "stock trade" interaction that is initiated by the client and handled by the server. That involves a private "replyTo" Queue that is sent by the client within the order request Message itself.

The Server's core configuration is in the RabbitServerConfiguration class within the org.springframework.amqp.rabbit.stocks.config.server package. It extends the AbstractStockAppRabbitConfiguration. That is where the resources common to the Server and Client(s) are defined, including the market data Topic Exchange (whose name is *app.stock.marketdata*) and the Queue that the Server exposes for stock trades (whose name is *app.stock.request*). In that common configuration file, you will also see that a JsonMessageConverter is configured on the RabbitTemplate.

The Server-specific configuration consists of 2 things. First, it configures the market data exchange on the RabbitTemplate so that it does not need to provide that exchange name with every call to send a Message. It does this within an abstract callback method defined in the base configuration class.

```
public void configureRabbitTemplate(RabbitTemplate rabbitTemplate) {
    rabbitTemplate.setExchange(MARKET_DATA_EXCHANGE_NAME);
}
```

Secondly, the stock request queue is declared. It does not require any explicit bindings in this case, because it will be bound to the default no-name exchange with its own name as the routing key. As mentioned earlier, the AMQP specification defines that behavior.

```
@Bean
public Queue stockRequestQueue() {
    return new Queue(STOCK_REQUEST_QUEUE_NAME);
}
```

Now that you've seen the configuration of the Server's AMQP resources, navigate to the *org.springframework.amqp.rabbit.stocks* package under the *src/test/java* directory. There you will see the actual Server class that provides a main() method. It creates an ApplicationContext based on the *server-bootstrap.xml* config file. In there you will see the scheduled task that publishes dummy market data. That configuration relies upon Spring 3.0's "task" namespace support. The bootstrap config file also imports a few other files. The most interesting one is *server-messaging.xml* which is directly under *src/main/resources*. In there you will see the "messageListenerContainer" bean that is responsible for handling the stock trade requests. Finally have a look at the "serverHandler" bean that is defined in "server-handlers.xml" (also in *src/main/resources*). That bean is an instance of the ServerHandler class and is a good example of a Message-driven POJO that is also capable of sending reply Messages. Notice that it is not itself coupled to the framework or any of the AMQP concepts. It simply accepts a TradeRequest and returns a TradeResponse.

```
public TradeResponse handleMessage(TradeRequest tradeRequest) { ...
}
```

Now that we've seen the most important configuration and code for the Server, let's turn to the Client. The best starting point is probably RabbitClientConfiguration within the *org.springframework.amqp.rabbit.stocks.config.client* package. Notice that it declares two queues without providing explicit names.

```
@Bean
public Queue marketDataQueue() {
    return amqpAdmin().declareQueue();
}

@Bean
public Queue traderJoeQueue() {
    return amqpAdmin().declareQueue();
}
```

Those are private queues, and unique names will be generated automatically. The first generated queue is used by the Client to bind to the market data exchange that has been exposed by the Server. Recall that in AMQP, consumers interact with Queues while producers interact with Exchanges. The "binding" of Queues to Exchanges is what instructs the broker to deliver, or route, messages from a given Exchange to a Queue. Since the market data exchange is a Topic Exchange, the binding can be expressed with a routing pattern. The RabbitClientConfiguration declares that with a Binding object, and that object is generated with the BindingBuilder's fluent API.

```
@Value("${stocks.quote.pattern}")
private String marketDataRoutingKey;

@Bean
public Binding marketDataBinding() {
    return BindingBuilder.bind(
        marketDataQueue()).to(marketDataExchange()).with(marketDataRoutingKey);
}
```

Notice that the actual value has been externalized in a properties file ("client.properties" under src/main/resources), and that we are using Spring's @Value annotation to inject that value. This is generally a good idea, since otherwise the value would have been hardcoded in a class and unmodifiable without recompilation. In this case, it makes it much easier to run multiple versions of the Client while making changes to the routing pattern used for binding. Let's try that now.

Start by running org.springframework.amqp.rabbit.stocks.Server and then org.springframework.amqp.rabbit.stocks.Client. You should see dummy quotes for NASDAQ stocks because the current value associated with the *stocks.quote.pattern* key in client.properties is

app.stock.quotes.nasdaq.. Now, while keeping the existing Server and Client running, change that property value to app.stock.quotes.nyse. and start a second Client instance. You should see that the first client is still receiving NASDAQ quotes while the second client receives NYSE quotes. You could instead change the pattern to get all stocks or even an individual ticker.

The final feature we'll explore is the request-reply interaction from the Client's perspective. Recall that we have already seen the ServerHandler that is accepting TradeRequest objects and returning TradeResponse objects. The corresponding code on the Client side is RabbitStockServiceGateway in the *org.springframework.amqp.rabbit.stocks.gateway* package. It delegates to the RabbitTemplate in order to send Messages.

```
public void send(TradeRequest tradeRequest) {
    getRabbitTemplate().convertAndSend(tradeRequest, new MessagePostProcessor() {
        public Message postProcessMessage(Message message) throws AmqpException {
            message.getMessageProperties().setReplyTo(new Address(defaultReplyToQueue));
            try {
                message.getMessageProperties().setCorrelationId(
                    UUID.randomUUID().toString().getBytes("UTF-8"));
            }
            catch (UnsupportedEncodingException e) {
                throw new AmqpException(e);
            }
            return message;
        }
    });
}
```

Notice that prior to sending the message, it sets the "replyTo" address. It's providing the queue that was generated by the "traderJoeQueue" bean definition shown above. Here's the @Bean definition for the StockServiceGateway class itself.

```
@Bean
public StockServiceGateway stockServiceGateway() {
    RabbitStockServiceGateway gateway = new RabbitStockServiceGateway();
    gateway.setRabbitTemplate(rabbitTemplate());
    gateway.setDefaultReplyToQueue(traderJoeQueue());
    return gateway;
}
```

If you are no longer running the Server and Client, start them now. Try sending a request with the format of *100 TCKR*. After a brief artificial delay that simulates "processing" of the request, you should see a confirmation message appear on the Client.

4. Spring Integration - Reference

This part of the reference documentation provides a quick introduction to the AMQP support within the Spring Integration project.

4.1 Spring Integration AMQP Support

Introduction

The Spring Integration project includes AMQP Channel Adapters and Gateways that build upon the Spring AMQP project. Those adapters are developed and released in the Spring Integration project. In Spring Integration, "Channel Adapters" are unidirectional (one-way) whereas "Gateways" are bidirectional (request-reply). We provide an inbound-channel-adapter, outbound-channel-adapter, inbound-gateway, and outbound-gateway.

Since the AMQP adapters are part of the Spring Integration release, the documentation will be available as part of the Spring Integration distribution. As a taster, we just provide a quick overview of the main features here.

Inbound Channel Adapter

To receive AMQP Messages from a Queue, configure an <inbound-channel-adapter>

```
<amqp:inbound-channel-adapter channel="fromAMQP"
                              queue-names="some.queue"
                              connection-factory="rabbitConnectionFactory"/>
```

Outbound Channel Adapter

To send AMQP Messages to an Exchange, configure an <outbound-channel-adapter>. A *routing-key* may optionally be provided in addition to the exchange name.

```
<amqp:outbound-channel-adapter channel="toAMQP"
                               exchange-name="some.exchange"
                               routing-key="foo"
                               amqp-template="rabbitTemplate"/>
```

Inbound Gateway

To receive an AMQP Message from a Queue, and respond to its reply-to address, configure an <inbound-gateway>.

```
<amqp:inbound-gateway request-channel="fromAMQP"
                      reply-channel="toAMQP"
                      queue-names="some.queue"
                      connection-factory="rabbitConnectionFactory"/>
```

Outbound Gateway

To send AMQP Messages to an Exchange and receive back a response from a remote client, configure an <outbound-gateway>. A *routing-key* may optionally be provided in addition to the exchange name.

```
<amqp:outbound-gateway request-channel="toAMQP"
                       reply-channel="fromAMQP"
                       exchange-name="some.exchange"
                       routing-key="foo"
                       amqp-template="rabbitTemplate"/>
```

5. Other Resources

In addition to this reference documentation, there exist a number of other resources that may help you learn about AMQP.

5.1 Further Reading

For those who are not familiar with AMQP, the specification is actually quite readable. It is of course the authoritative source of information, and the Spring AMQP code should be very easy to understand for anyone who is familiar with the spec. Our current implementation of the RabbitMQ support is based on their 2.8.x version, and it officially supports AMQP 0.8 and 0.9.1. We recommend reading the 0.9.1 document.

There are many great articles, presentations, and blogs available on the RabbitMQ Getting Started page. Since that is currently the only supported implementation for Spring AMQP, we also recommend that as a general starting point for all broker-related concerns.
