Part I. Preface

1. About the documentation

The Spring Cloud Data Flow for Apache Yarn reference guide is available as [html](#), [pdf](#) and [epub](#) documents. The latest copy is available at docs.spring.io/spring-cloud-dataflow-server-yarn/docs/current-SNAPSHOT/reference/html/.

Copies of this document may be made for your own use and for distribution to others, provided that you do not charge any fee for such copies and further provided that each copy contains this Copyright Notice, whether distributed in print or electronically.

2. Getting help

Having trouble with Spring Cloud Data Flow, We'd like to help!

- Try the [How-to's](#) — they provide solutions to the most common questions.
- Ask a question - we monitor stackoverflow.com for questions tagged with [spring-cloud](#).
- Report bugs with Spring Cloud Dataflow for Apache YARN at github.com/spring-cloud/spring-cloud-dataflow-server-yarn/issues.

Note

All of Spring Cloud Data Flow is open source, including the documentation! If you find problems with the docs; or if you just want to improve them, please [get involved](#).

Part II. Introduction

3. Introducing Spring Cloud Data Flow for Apache YARN project

This project provides support for orchestrating long-running (*streaming*) and short-lived (*task/batch*) data microservices to Apache YARN.

4. Spring Cloud Data Flow

Spring Cloud Data Flow is a cloud-native orchestration service for composable data microservices on modern runtimes. With Spring Cloud Data Flow, developers can create and orchestrate data pipelines for common use cases such as data ingest, real-time analytics, and data import/export.

The Spring Cloud Data Flow architecture consists of a server that deploys [Streams](#) and [Tasks](#). Streams are defined using a [DSL](#) or visually through the browser based designer UI. Streams are based on the [Spring Cloud Stream](#) programming model while Tasks are based on the [Spring Cloud Task](#) programming model. The sections below describe more information about creating your own custom Streams and Tasks

For more details about the core architecture components and the supported features, please review Spring Cloud Data Flow's [core reference guide](#). There're several [samples](#) available for reference.

5. Spring Cloud Stream

Spring Cloud Stream is a framework for building message-driven microservice applications. Spring Cloud Stream builds upon Spring Boot to create standalone, production-grade Spring applications, and uses Spring Integration to provide connectivity to message brokers. It provides opinionated configuration of middleware from several vendors, introducing the concepts of persistent publish-subscribe semantics, consumer groups, and partitions.

For more details about the core framework components and the supported features, please review Spring Cloud Stream's [reference guide](#).

There's a rich ecosystem of Spring Cloud Stream [Application-Starters](#) that can be used either as standalone data microservice applications or in Spring Cloud Data Flow. For convenience, we have generated RabbitMQ and Apache Kafka variants of these application-starters that are available for use from [Maven Repo](#) and [Docker Hub](#) as maven artifacts and docker images, respectively.

Do you have a requirement to develop custom applications? No problem. Refer to this guide to create [custom stream applications](#). There're several [samples](#) available for reference.

6. Spring Cloud Task

Spring Cloud Task makes it easy to create short-lived microservices. We provide capabilities that allow short-lived JVM processes to be executed on demand in a production environment.

For more details about the core framework components and the supported features, please review Spring Cloud Task's [reference guide](#).

There's a rich ecosystem of Spring Cloud Task [Application-Starters](#) that can be used either as standalone data microservice applications or in Spring Cloud Data Flow. For convenience, the generated application-starters are available for use from [Maven Repo](#). There are several [samples](#) available for reference.

Part III. Architecture

7. Introduction

Spring Cloud Data Flow simplifies the development and deployment of applications focused on data processing use-cases. The major concepts of the architecture are Applications, the Data Flow Server, and the target runtime.

Applications come in two flavors

- Long lived Stream applications where an unbounded amount of data is consumed or produced via messaging middleware.
- Short lived Task applications that process a finite set of data and then terminate.

Depending on the runtime, applications can be packaged in two ways

- Spring Boot uber-jar that is hosted in a maven repository, file, http or any other Spring resource implementation.
- Docker

The runtime is the place where applications execute. The target runtimes for applications are platforms that you may already be using for other application deployments.

The supported runtimes are

- Cloud Foundry
- Apache YARN
- Kubernetes
- Apache Mesos
- Local Server for development

There is a deployer Service Provider Interface (SPI) that enables you to extend Data Flow to deploy onto other runtimes, for example to support Docker Swarm. There are community implementations of Hashicorp's Nomad and RedHat Openshift is available. We look forward to working with the community for further contributions!

The component that is responsible for deploying applications to a runtime is the Data Flow Server. There is a Data Flow Server executable jar provided for each of the target runtimes. The Data Flow server is responsible for interpreting

- A stream DSL that describes the logical flow of data through multiple applications.
- A deployment manifest that describes the mapping of applications onto the runtime. For example, to set the initial number of instances, memory requirements, and data partitioning.

As an example, the DSL to describe the flow of data from an http source to an Apache Cassandra sink would be written as "http | cassandra". These names in the DSL are registered with the Data Flow Server and map onto application artifacts that can be hosted in Maven or Docker repositories. Many source, processor, and sink applications for common use-cases (e.g. jdbc, hdfs, http, router) are provided by the Spring Cloud Data Flow team. The pipe symbol represents the communication between the two applications via messaging middleware. The two messaging middleware brokers that are supported are

- Apache Kafka
- RabbitMQ

In the case of Kafka, when deploying the stream, the Data Flow server is responsible to create the topics that correspond to each pipe symbol and configure each application to produce or consume from the topics so the desired flow of data is achieved.

The interaction of the main components is shown below

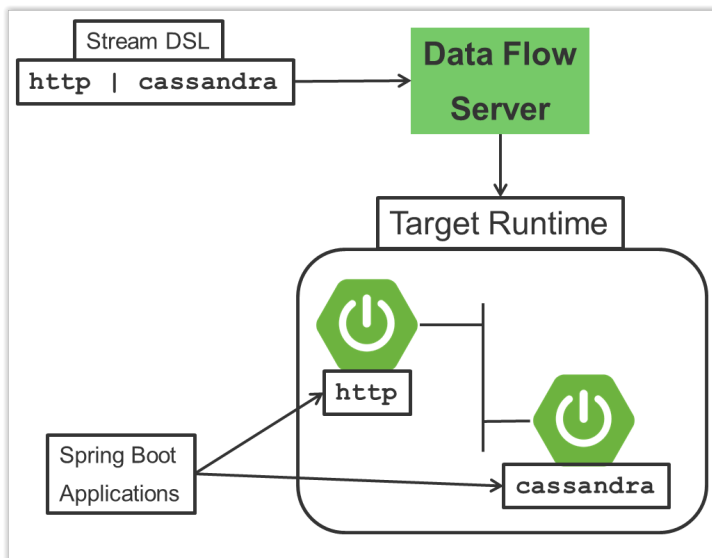

Figure 7.1. The Spring Cloud Data High Level Architecture

In this diagram a DSL description of a stream is POSTed to the Data Flow Server. Based on the mapping of DSL application names to Maven and Docker artifacts, the http-source and cassandra-sink applications are deployed on the target runtime.

8. Microservice Architectural Style

The Data Flow Server deploys applications onto the target runtime that conform to the microservice architectural style. For example, a stream represents a high level application that consists of multiple small microservice applications each running in their own process. Each microservice application can be scaled up or down independent of the other and each has their own versioning lifecycle.

Both Streaming and Task based microservice applications build upon Spring Boot as the foundational library. This gives all microservice applications functionality such as health checks, security, configurable logging, monitoring and management functionality, as well as executable JAR packaging.

It is important to emphasise that these microservice applications are 'just apps' that you can run by yourself using 'java -jar' and passing in appropriate configuration properties. We provide many common microservice applications for common operations so you don't have to start from scratch when addressing common use-cases which build upon the rich ecosystem of Spring Projects, e.g Spring Integration, Spring Data, Spring Hadoop and Spring Batch. Creating your own microservice application is similar to creating other Spring Boot applications, you can start using the Spring Initializr web site or the UI to create the basic scaffolding of either a Stream or Task based microservice.

In addition to passing in the appropriate configuration to the applications, the Data Flow server is responsible for preparing the target platform's infrastructure so that the application can be deployed. For example, in Cloud Foundry it would be binding specified services to the applications and executing the 'cf push' command for each application. For Kubernetes it would be creating the replication controller, service, and load balancer.

The Data Flow Server helps simplify the deployment of multiple applications onto a target runtime, but one could also opt to deploy each of the microservice applications manually and not use Data Flow at all. This approach might be more appropriate to start out with for small scale deployments, gradually adopting the convenience and consistency of Data Flow as you develop more applications. Manual deployment of Stream and Task based microservices is also a useful educational exercise that will help you better understand some of the automatic applications configuration and platform targeting steps that the Data Flow Server provides.

8.1 Comparison to other Platform architectures

Spring Cloud Data Flow's architectural style is different than other Stream and Batch processing platforms. For example in Apache Spark, Apache Flink, and Google Cloud Dataflow applications run on a dedicated compute engine cluster. The nature of the compute engine gives these platforms a richer environment for performing complex calculations on the data as compared to Spring Cloud Data Flow, but it introduces complexity of another execution environment that is often not needed when creating data centric applications. That doesn't mean you cannot do real time data computations when using Spring Cloud Data Flow. Refer to the analytics section which describes the integration of Redis to handle common counting based use-cases as well as the RxJava integration for functional API driven analytics use-cases, such as time-sliding-window and moving-average among others.

Similarly, Apache Storm, Hortonworks DataFlow and Spring Cloud Data Flow's predecessor, Spring XD, use a dedicated application execution cluster, unique to each product, that determines where your code should execute on the cluster and perform health checks to ensure that long lived applications are restarted if they fail. Often, framework specific interfaces are required to be used in order to correctly "plug in" to the cluster's execution framework.

As we discovered during the evolution of Spring XD, the rise of multiple container frameworks in 2015 made creating our own runtime a duplication of efforts. There is no reason to build your own resource management mechanics, when there are multiple runtime platforms that offer this functionality already. Taking these considerations into account is what made us shift to the current architecture where we delegate the execution to popular runtimes, runtimes that you may already be using for other purposes. This is an advantage in that it reduces the cognitive distance for creating and managing data centric applications as many of the same skills used for deploying other end-user/web applications are applicable.

9. Streaming Applications

While Spring Boot provides the foundation for creating DevOps friendly microservice applications, other libraries in the Spring ecosystem help create Stream based microservice applications. The most important of these is Spring Cloud Stream.

The essence of the Spring Cloud Stream programming model is to provide an easy way to describe multiple inputs and outputs of an application that communicate over messaging middleware. These input and outputs map onto Kafka topics or Rabbit exchanges and queues. Common application configuration for a Source that generates data, a Process that consumes and produces data and a Sink that consumes data is provided as part of the library.

9.1 Imperative Programming Model

Spring Cloud Stream is most closely integrated with Spring Integration's imperative "event at a time" programming model. This means you write code that handles a single event callback. For example,

```
@EnableBinding(Sink.class)
public class LoggingSink {

    @StreamListener(Sink.INPUT)
    public void log(String message) {
        System.out.println(message);
    }
}
```

In this case the String payload of a message coming on the input channel, is handed to the log method. The `@EnableBinding` annotation is what is used to tie together the input channel to the external middleware.

9.2 Functional Programming Model

However, Spring Cloud Stream can support other programming styles. The use of reactive APIs where incoming and outgoing data is handled as continuous data flows and it defines how each individual message should be handled. You can also use operators that describe functional transformations from inbound to outbound data flows. The upcoming versions will support Apache Kafka's KStream API in the programming model.

10. Streams

10.1 Topologies

The Stream DSL describes linear sequences of data flowing through the system. For example, in the stream definition `http | transformer | cassandra`, each pipe symbol connects the application on the left to the one on the right. Named channels can be used for routing and to fan out data to multiple messaging destinations.

Taps can be used to ‘listen in’ to the data that is flowing across any of the pipe symbols. Taps can be used as sources for new streams with an independent life cycle.

10.2 Concurrency

For an application that will consume events, Spring Cloud Stream exposes a concurrency setting that controls the size of a thread pool used for dispatching incoming messages. See the `1.2.1.RELEASE#_consumer_properties[Consumer properties]` documentation for more information.

10.3 Partitioning

A common pattern in stream processing is to partition the data as it moves from one application to the next. Partitioning is a critical concept in stateful processing, for either performance or consistency reasons, to ensure that all related data is processed together. For example, in a time-windowed average calculation example, it is important that all measurements from any given sensor are processed by the same application instance. Alternatively, you may want to cache some data related to the incoming events so that it can be enriched without making a remote procedure call to retrieve the related data.

Spring Cloud Data Flow supports partitioning by configuring Spring Cloud Stream’s output and input bindings. Spring Cloud Stream provides a common abstraction for implementing partitioned processing use cases in a uniform fashion across different types of middleware. Partitioning can thus be used whether the broker itself is naturally partitioned (e.g., Kafka topics) or not (e.g., RabbitMQ). The following image shows how data could be partitioned into two buckets, such that each instance of the average processor application consumes a unique set of data.

Figure 10.1. Spring Cloud Stream Partitioning

To use a simple partitioning strategy in Spring Cloud Data Flow, you only need set the instance count for each application in the stream and a `partitionKeyExpression` producer property when deploying the stream. The `partitionKeyExpression` identifies what part of the message will be used as the key to partition data in the underlying middleware. An `ingest` stream can be defined as `http | averageprocessor | cassandra` (Note that the Cassandra sink isn’t shown in the diagram above).

Suppose the payload being sent to the http source was in JSON format and had a field called `sensorId`. Deploying the stream with the shell command `stream deploy ingest --propertiesFile ingestStream.properties` where the contents of the file `ingestStream.properties` are

```
deployer.http.count=3
deployer.averageprocessor.count=2
app.http.producer.partitionKeyExpression=payload.sensorId
```

will deploy the stream such that all the input and output destinations are configured for data to flow through the applications but also ensure that a unique set of data is always delivered to each `averageprocessor` instance. In this case the default algorithm is to evaluate `payload.sensorId % partitionCount` where the `partitionCount` is the application count in the case of RabbitMQ and the partition count of the topic in the case of Kafka.

Please refer to [the section called “Passing stream partition properties during stream deployment”](#) for additional strategies to partition streams during deployment and how they map onto the underlying 1.2.1.RELEASE#_partitioning[Spring Cloud Stream Partitioning properties].

Also note, that you can’t currently scale partitioned streams. Read the section [Section 14.3, “Scaling at runtime”](#) for more information.

10.4 Message Delivery Guarantees

Streams are composed of applications that use the Spring Cloud Stream library as the basis for communicating with the underlying messaging middleware product. Spring Cloud Stream also provides an opinionated configuration of middleware from several vendors, in particular providing 1.2.1.RELEASE#_persistent_publish_subscribe_support[persistent publish-subscribe semantics].

The 1.2.1.RELEASE#_binders[Binder abstraction] in Spring Cloud Stream is what connects the application to the middleware. There are several configuration properties of the binder that are portable across all binder implementations and some that are specific to the middleware.

For consumer applications there is a retry policy for exceptions generated during message handling. The retry policy is configured using the 1.2.1.RELEASE#_consumer_properties[common consumer properties] `maxAttempts`, `backOffInitialInterval`, `backOffMaxInterval`, and `backOffMultiplier`. The default values of these properties will retry the callback method invocation 3 times and wait one second for the first retry. A backoff multiplier of 2 is used for the second and third attempts.

When the number of retry attempts has exceeded the `maxAttempts` value, the exception and the failed message will become the payload of a message and be sent to the application’s error channel. By default, the default message handler for this error channel logs the message. You can change the default behavior in your application by creating your own message handler that subscribes to the error channel.

Spring Cloud Stream also supports a configuration option for both Kafka and RabbitMQ binder implementations that will send the failed message and stack trace to a dead letter queue. The dead letter queue is a destination and its nature depends on the messaging middleware (e.g in the case of Kafka it is a dedicated topic). To enable this for RabbitMQ set the 1.2.1.RELEASE#_rabbitmq_consumer_properties[consumer properties] `republishToDlq` and `autoBindDlq` and the 1.2.1.RELEASE#_rabbit_producer_properties[producer property] `autoBindDlq` to true when deploying the stream. To always apply these producer and consumer properties when deploying streams, configure them as [common application properties](#) when starting the Data Flow server.

Additional messaging delivery guarantees are those provided by the underlying messaging middleware that is chosen for the application for both producing and consuming applications. Refer to the [Kafka 1.2.1.RELEASE#_kafka_consumer_properties\[Consumer\]](#) and [1.2.1.RELEASE#_kafka_producer_properties\[Producer\]](#) and [Rabbit 1.2.1.RELEASE#_rabbitmq_consumer_properties\[Consumer\]](#) and [1.2.1.RELEASE#_rabbit_producer_properties\[Producer\]](#) documentation for more details. You will find extensive declarative support for all the native QOS options.

11. Analytics

Spring Cloud Data Flow is aware of certain Sink applications that will write counter data to Redis and provides an REST endpoint to read counter data. The types of counters supported are

- [Counter](#) - Counts the number of messages it receives, optionally storing counts in a separate store such as redis.
- [Field Value Counter](#) - Counts occurrences of unique values for a named field in a message payload
- [Aggregate Counter](#) - Stores total counts but also retains the total count values for each minute, hour day and month.

It is important to note that the timestamp that is used in the aggregate counter can come from a field in the message itself so that out of order messages are properly accounted.

12. Task Applications

The Spring Cloud Task programming model provides:

- Persistence of the Task's lifecycle events and exit code status.
- Lifecycle hooks to execute code before or after a task execution.
- Emit task events to a stream (as a source) during the task lifecycle.
- Integration with Spring Batch Jobs.

13. Data Flow Server

13.1 Endpoints

The Data Flow Server uses an embedded servlet container and exposes REST endpoints for creating, deploying, undeploying, and destroying streams and tasks, querying runtime state, analytics, and the like. The Data Flow Server is implemented using Spring's MVC framework and the [Spring HATEOAS](#) library to create REST representations that follow the HATEOAS principle.

Figure 13.1. The Spring Cloud Data Flow Server

13.2 Customization

Each Data Flow Server executable jar targets a single runtime by delegating to the implementation of the deployer Service Provider Interface found on the classpath.

We provide a Data Flow Server executable jar that targets a single runtime. The Data Flow server delegates to the implementation of the deployer Service Provider Interface found on the classpath. In the current version, there are no endpoints specific to a target runtime, but may be available in future releases as a convenience to access runtime specific features

While we provide a server executable for each of the target runtimes you can also create your own customized server application using Spring Initializr. This lets you add or remove functionality relative to the executable jar we provide. For example, adding additional security implementations, custom

endpoints, or removing Task or Analytics REST endpoints. You can also enable or disable some features through the use of feature toggles.

13.3 Security

The Data Flow Server executable jars support basic http, LDAP(S), File-based, and OAuth 2.0 authentication to access its endpoints. Refer to the [security section](#) for more information.

Authorization via groups is planned for a future release.

14. Runtime

14.1 Fault Tolerance

The target runtimes supported by Data Flow all have the ability to restart a long lived application should it fail. Spring Cloud Data Flow sets up whatever health probe is required by the runtime environment when deploying the application.

The collective state of all applications that comprise the stream is used to determine the state of the stream. If an application fails, the state of the stream will change from 'deployed' to 'partial'.

14.2 Resource Management

Each target runtime lets you control the amount of memory, disk and CPU that is allocated to each application. These are passed as properties in the deployment manifest using key names that are unique to each runtime. Refer to the each platforms server documentation for more information.

14.3 Scaling at runtime

When deploying a stream, you can set the instance count for each individual application that comprises the stream. Once the stream is deployed, each target runtime lets you control the target number of instances for each individual application. Using the APIs, UIs, or command line tools for each runtime, you can scale up or down the number of instances as required. Future work will provide a portable command in the Data Flow Server to perform this operation.

Currently, this is not supported with the Kafka binder (based on the 0.8 simple consumer at the time of the release), as well as partitioned streams, for which the suggested workaround is redeploying the stream with an updated number of instances. Both cases require a static consumer set up based on information about the total instance count and current instance index, a limitation intended to be addressed in future releases. For example, Kafka 0.9 and higher provides good infrastructure for scaling applications dynamically and will be available as an alternative to the current Kafka 0.8 based binder in the near future. One specific concern regarding scaling partitioned streams is the handling of local state, which is typically reshuffled as the number of instances is changed. This is also intended to be addressed in the future versions, by providing first class support for local state management.

14.4 Application Versioning

Application versioning, that is upgrading or downgrading an application from one version to another, is not directly supported by Spring Cloud Data Flow. You must rely on specific target runtime features to perform these operational tasks.

The roadmap for Spring Cloud Data Flow will deploy applications that are compatible with Spinnaker to manage the complete application lifecycle. This also includes automated canary analysis backed by application metrics. Portable commands in the Data Flow server to trigger pipelines in Spinnaker are also planned.

Part IV. Spring Cloud

Data Flow Runtime

Data flow runtime can be deployed and used with *YARN* in two different ways, firstly using it directly with a *YARN* cluster and secondly letting *Apache Ambari* deploy it into its cluster as a service. Difference between these two deployment types is that *YARN* only provides a raw runtime environment for containers where user is required to setup all needed dependencies while *Apache Ambari* will try to focus on easy deployment where minimum set of required services exist in ambari managed cluster.

15. Deploying on YARN

The server application is run as a standalone application. All applications used for streams and tasks will be deployed on the YARN cluster that is targeted by the server.

15.1 Prerequisites

These requirements are not something yarn runtime needs but generally what dataflow core needs.

- Rabbit - If dataflow apps using rabbit bindings are used.
- Kafka - If dataflow apps using kafka bindings are used.
- DB - we currently use embedded H2 database, though any supported DB can be configured.

15.2 Download and Extract Distribution

Download the Spring Cloud Data Flow YARN distribution ZIP file which includes the Server and the Shell apps:

```
$ wget http://repo.spring.io/release/org/springframework/cloud/dist/spring-cloud-dataflow-server-yarn-dist/1.2.1.RELEASE/spring-cloud-dataflow-server-yarn-dist-1.2.1.RELEASE.zip
```

Unzip the distribution ZIP file and change to the directory containing the deployment files.

```
$ cd spring-cloud-dataflow-server-yarn-1.2.1.RELEASE
```

15.3 Configure Settings

Generic runtime settings can be changed in `config/servers.yml`. Dedicated section [Chapter 17, Configuring Runtime Settings and Environment](#) contains detailed information about configuration.

`servers.yml` file is a central place to share common configuration as it is added to Boot based jvm processes via option `-Dspring.config.location=servers.yml`.

15.4 Start Server

If this is the first time deploying make sure the user that runs the *Server* app has rights to create and write to `/dataflow` directory in `hdfs`. If there is an existing deployment on `hdfs` remove it using:

```
$ hdfs dfs -rm -R /dataflow
```

Start the Spring Cloud Data Flow Server app for YARN

```
$ ./bin/dataflow-server-yarn
```

15.5 Connect Shell

start `spring-cloud-dataflow-shell`

```
$ ./bin/dataflow-shell
```

Shell in a distribution package contains extension commands for a `hdfs` file system.

```
dataflow:>hadoop fs
hadoop fs cat          hadoop fs copyFromLocal  hadoop fs copyToLocal  hadoop fs expunge
hadoop fs ls           hadoop fs mkdir      hadoop fs mv            hadoop fs rm
dataflow:>hadoop fs ls /
rwxrwxrwx root          supergroup 0 2016-07-25 06:54:15 /
rwxrwxrwx jvalkealahti supergroup 0 2016-07-25 06:58:38 /dataflow
rwxr-xr-x jvalkealahti supergroup 0 2016-07-25 07:31:32 /repo
rwxrwxrwx root          supergroup 0 2016-07-20 16:25:31 /tmp
rwxrwxrwx jvalkealahti supergroup 0 2015-10-29 10:59:24 /user
```

**Tip**

You can configure server address automatically by placing it in a configuration using key `dataflow.uri`.

15.6 Register Applications

By default, the application registry will be empty. If you would like to register all out-of-the-box stream applications built with the RabbitMQ binder in bulk, you can with the following command. For more details, review how to [register applications](#).

```
dataflow:>app import --uri http://bit.ly/stream-applications-rabbit-maven
```

Sourcing Applications from HDFS

YARN integration also allows you to store registered applications directly in HDFS instead of relying on maven or any other resolution. Only thing to change during a registration is to use `hdfs` address as shown below.

```
dataflow:>app register --name ftp --type sink --uri hdfs://dataflow/artifacts/repo/ftp-sink-
kafka-1.0.0.RC1.jar
```

15.7 Create Stream

Create a stream:

```
dataflow:>stream create --name foostream --definition "time|log" --deploy
```

List streams:

```
dataflow:>stream list
#####
#Stream Name#Stream Definition# Status #
#####
#foostream   #time|log          #deployed#
#####
```

After some time, destroy the stream:

```
dataflow:>stream destroy --name foostream
```

The YARN application is pushed and started automatically during a stream deployment process. Once all streams are destroyed the YARN application will exit.

15.8 Create Task

Create and launch task:

```
dataflow:>task create --name footask --definition "timestamp"
Created new task 'footask'
dataflow:>task launch --name footask
Launched task 'footask'
```

Launch tasks from streams:

`task-launcher-yarn-sink` itself bundles a *YARN Deployer* but doesn't push any apps into hdfs, thus pushed app needs to exist and match a deployer version `task-launcher-yarn-sink` uses.

In below sample we use `tasklaunchrequest` processor to pass needed properties into `task-launcher-yarn` sink. We explicitly defined `appVersion` as `appv1` which you would have pushed into hdfs prior running this stream. With this processor you also need to define a `uri` for a task application itself.

```
stream create --name launchertest --definition "http
--server.port=9000|tasklaunchrequest
--deployment-properties=spring.cloud.deployer.yarn.app.appVersion=appv1
--uri=hdfs:/dataflow/repo/timestamp-task.jar|task-launcher-yarn"
--deploy
```

To fire up a task just post a dummy message into `http` source.

```
http post --target http://localhost:9000 --data empty
```

Note

Using `http` source in YARN difficult as you don't immediately know on which cluster node that source app is running.

15.9 Using YARN Cli

Overall app status can be seen from *YARN Resource Manager UI* or using *Spring YARN CLI* which gives more info about running containers within an app itself.

```
$ ./bin/dataflow-server-yarn-cli shell
```

Check YARN App Statuses

When stream has been submitted YARN shows it as `ACCEPTED` before its turned to `RUNNING` state.

```
$ submitted
APPLICATION ID          USER          NAME          QUEUE  TYPE  STARTTIME
FINISHTIME  STATE  FINALSTATUS  ORIGINAL  TRACKING URL
-----
application_1461658614481_0001  jvalkealahti  scdstream:app:foostream  default  DATAFLOW  26/04/16
16:27  N/A      ACCEPTED  UNDEFINED
-----

$ submitted
APPLICATION ID          USER          NAME          QUEUE  TYPE  STARTTIME
FINISHTIME  STATE  FINALSTATUS  ORIGINAL  TRACKING URL
-----
application_1461658614481_0001  jvalkealahti  scdstream:app:foostream  default  DATAFLOW  26/04/16
16:27  N/A      RUNNING  UNDEFINED  http://192.168.1.96:58580
```

More info about internals for stream apps can be queried by `clustersinfo` and `clusterinfo` commands:

```
$ clustersinfo -a application_1461658614481_0001
```

```

CLUSTER ID
-----
foostream:log
foostream:time

$ clusterinfo -a application_1461658614481_0001 -c foostream:time
CLUSTER STATE  MEMBER COUNT
-----
RUNNING        1

```

After stream is undeployed YARN app should close itself automatically:

```

$ submitted -v
APPLICATION ID      USER      NAME      QUEUE    TYPE    STARTTIME
FINISHTIME        STATE      FINALSTATUS  ORIGINAL TRACKING URL
-----
application_1461658614481_0001  jvalkealahti  scdstream:app:foostream  default  DATAFLOW  26/04/16
16:27  26/04/16  16:28  FINISHED  SUCCEEDED

```

Launching a task will be shown in RUNNING state while app is executing its batch jobs:

```

$ submitted -v
APPLICATION ID      USER      NAME      QUEUE    TYPE    STARTTIME
FINISHTIME        STATE      FINALSTATUS  ORIGINAL TRACKING URL
-----
application_1461658614481_0002  jvalkealahti  scdtask:timestamp  default  DATAFLOW  26/04/16
16:29  N/A      RUNNING  UNDEFINED  http://192.168.1.96:39561
application_1461658614481_0001  jvalkealahti  scdstream:app:foostream  default  DATAFLOW  26/04/16
16:27  26/04/16  16:28  FINISHED  SUCCEEDED

$ submitted -v
APPLICATION ID      USER      NAME      QUEUE    TYPE    STARTTIME
FINISHTIME        STATE      FINALSTATUS  ORIGINAL TRACKING URL
-----
application_1461658614481_0002  jvalkealahti  scdtask:timestamp  default  DATAFLOW  26/04/16
16:29  26/04/16  16:29  FINISHED  SUCCEEDED
application_1461658614481_0001  jvalkealahti  scdstream:app:foostream  default  DATAFLOW  26/04/16
16:27  26/04/16  16:28  FINISHED  SUCCEEDED

```

Push Apps

Yarn applications needed for a dataflow can be pushed manually into hdfs with a given version which default to app.

```

Spring YARN Cli (v2.4.0.RELEASE)
Hit TAB to complete. Type 'help' and hit RETURN for help, and 'exit' to quit.
$ push -t STREAM
New version installed
$ push -t TASK
New version installed
$ push -t TASK -v appv1
New version installed

```

After above commands base directories for different app versions would look like as shown below. Streams and tasks can then use different versions which allows to use alternate configurations.

```

/dataflow/apps/stream/app
/dataflow/apps/task/app
/dataflow/apps/task/appv1

```

Note

Push happens automatically when stream is deployer or task launched.

15.10 Using Metric Collectors

We package three different metrics collector implementations, one for *RabbitMQ* and two for different *Kafka* versions. They can be started using shell scripts, `dataflow-server-metrics-collector-kafka-09`, `dataflow-server-metrics-collector-kafka-10` and `dataflow-server-metrics-collector-rabbit` respectively. These applications are not using `servers.yml` file for config, instead `collectors.yml` is used where custom settings can be placed.

Note

With `Kafka 0.10.1` and later, `kafka-10` should be used. With `Kafka 0.10.0` and earlier, `kafka-09` should be used.

16. Deploying on AMBARI

Ambari basically automates YARN installation instead of requiring user to do it manually. Also a lot of other configuration steps are automated as much as possible to ease overall installation process.

There is no difference on components deployed into ambari comparing of a manual usage with a separate YARN cluster. With ambari we simply package needed dataflow components into a rpm package so that it can be managed as an ambari service. After that ambari really only manage a runtime configuration of those components.

16.1 Install Ambari Server

Generally it is only needed to install `scdf-plugin-hdp` plugin into ambari server which adds needed service definitions.

```
[root@ambari-1 ~]# yum -y install ambari-server
[root@ambari-1 ~]# ambari-server setup -s
[root@ambari-1 ~]# wget -nv http://repo.spring.io/yum-release-local/scdf/1.2.1/scdf-release-1.2.1.repo -
O /etc/yum.repos.d/scdf-release-1.2.1.repo
[root@ambari-1 ~]# yum -y install scdf-plugin-hdp
[root@ambari-1 ~]# ambari-server start
```

Note

Ambari plugin only works for redhat6/redhat7 and related centos based systems for now.

16.2 Deploy Data Flow

When you create your cluster and choose a stack, make sure that `redhat6` or/and `redhat7` sections contains repository named `SCDF-1.2.1` and that it points to repo.spring.io/yum-release-local/scdf/1.2.1.

Ambari 2.4 contains major rewrites for stack definitions and how it is possible to integrate with those from external contributions. Our plugin will eventually integrate via extensions or management packs, but for now you need to choose stack marked as a *Default Version Definition* which contains correct yum repository. For example with HDP 2.5 you have two default choices, *HDP-2.5.0.0* and *HDP-2.5 (Default Version Definition)*. As mentioned you need to pick latter. With older ambari versions you don't have these new options.

From services choose Spring Cloud Data Flow and Kafka. Hdfs, Yarn and Zookeeper are forced dependencies.

Note

With Kafka you can do "one-click" installation while using Rabbit you need to provide appropriate connection settings as Rabbit is not part of a Ambari managed service.

Then in *Customize Services* what is really left for user to do is to customise settings if needed. Everything else is automatically configured. Technically it also allows you to switch to use rabbit by leaving Kafka out and defining rabbit settings there. But generally use of Kafka is a good choice.

Note

We also install H2 DB as service so that it can be accessed from every node.

16.3 Using Configuration

`servers.yml` file is also used to store common configuration with Ambari. Settings in *Advanced scdf-site* and *Custom scdf-site* are used to dynamically create a this file which is then copied over to hdfs when needed application files are deployed.

Every additional entry added via *Custom scdf-site* is added into `servers.yml` as is and overrides everything else in it.

Important

If ambari configuration is modified, you need to delete `/dataflow/apps/stream/app` and `/dataflow/apps/task/app` directories from hdfs for new settings to get applied. Files in above directories will not get overridden including generated `servers.yml` config file.

Change Datasource

Ambari managed service defaults to H2 database. We currently support using MySQL, PostgreSQL and HSQLDB as external datasources. Custom datasource configuration can be applied via *Custom scdf-site* as shown in below screenshot. After these settings are modified, all related services needs to be restarted.

Custom scdf-site

spring.datasource.password	spring	🔒	🟢	🔴
spring.datasource.url	jdbc:mysql://172.16.101.1:3306/scdf	🔒	🟢	🔴
spring.datasource.username	spring	🔒	🟢	🔴
spring.datasource.driverClassName	org.mariadb.jdbc.Driver	🔒	🟢	🔴

[Add Property ...](#)

Figure 16.1. Custom Datasource Config

Note

Managed service *SCDF H2 Database* can be stopped and put in a maintenance mode after custom datasource settings has been added.

17. Configuring Runtime Settings and Environment

This section describes how settings related to running YARN application can be modified.

17.1 Generic App Settings

All applications whether those are stream apps or task apps can be centrally configured with `servers.yml` as that file is passed to apps using `--spring.config.location='servers.yml'`.

17.2 Configuring Application Resources

Stream and task processes for application master and containers can be further tuned by setting memory and cpu settings. Also java options allow to define actual jvm options.

```
spring:
  cloud:
    deployer:
      yarn:
        app:
          streamappmaster:
            memory: 512m
            virtualCores: 1
            javaOpts: "-Xms512m -Xmx512m"
          streamcontainer:
            priority: 5
            memory: 256m
            virtualCores: 1
            javaOpts: "-Xms64m -Xmx256m"
          taskappmaster:
            memory: 512m
            virtualCores: 1
            javaOpts: "-Xms512m -Xmx512m"
          taskcontainer:
            priority: 10
            memory: 256m
            virtualCores: 1
            javaOpts: "-Xms64m -Xmx256m"
```

17.3 Configure Base Directory

Base directory where all needed files are kept defaults to `/dataflow` and can be changed using `baseDir` property.

```
spring:
  cloud:
    deployer:
      yarn:
        app:
          baseDir: /dataflow
```

17.4 Pre-populate Applications

Spring Cloud Data Flow app registration is based on URI's with various different endpoints. As mentioned in section [Chapter 18, How YARN Deployment Works](#) all applications are first stored into hdfs before application container is launched. Server can use `http`, `file`, `http` and `maven` based uris as well direct `hdfs` uris.

It is possible to place these applications directly into HDFS and register application based on that URI.

17.5 Configure Logging

Logging for all components is done centrally via `servers.yml` file using normal Spring Boot properties.

```
logging:
  level:
    org.apache.hadoop: INFO
    org.springframework.yarn: INFO
```

17.6 Configure Metrics

If metrics are enabled, needed settings are written into `servers.yml` files used by applications. Also specific settings are written into `collectors.yml` used by *SCDF Metrics Collector* service. You need to choose a correct collector type, its service port and output channel name.

Figure 17.1. Metrics Config

17.7 Global YARN Memory Settings

YARN Nodemanager is continuously tracking how much memory is used by individual YARN containers. If containers are using more memory than what the configuration allows, containers are simply killed by a Nodemanager. Application master controlling the app lifecycle is given a little more freedom meaning that Nodemanager is not that aggressive when making a decision when a container should be killed.

Important

These are global cluster settings and cannot be changed during an application deployment.

Lets take a quick look of memory related settings in YARN cluster and in YARN applications. Below xml config is what a default vanilla Apache Hadoop uses for memory related settings. Other distributions may have different defaults.

yarn.nodemanager.pmem-check-enabled

Enables a check for physical memory of a process. This check if enabled is directly tracking amount of memory requested for a YARN container.

yarn.nodemanager.vmem-check-enabled

Enables a check for virtual memory of a process. This setting is one which is usually causing containers of a custom YARN applications to get killed by a node manager. Usually the actual ratio

between physical and virtual memory is higher than a default 2.1 or bugs in a OS is causing wrong calculation of a used virtual memory.

yarn.nodemanager.vmem-pmem-ratio

Defines a ratio of allowed virtual memory compared to physical memory. This ratio simply defines how much virtual memory a process can use but the actual tracked size is always calculated from a physical memory limit.

yarn.scheduler.minimum-allocation-mb

Defines a minimum allocated memory for container.

Note

This setting also indirectly defines what is the actual physical memory limit requested during a container allocation. Actual physical memory limit is always going to be multiple of this setting rounded to upper bound. For example if this setting is left to default 1024 and container is requested with 512M, 1024M is going to be used. However if requested size is 1100M, actual size is set to 2048M.

yarn.scheduler.maximum-allocation-mb

Defines a maximum allocated memory for container.

yarn.nodemanager.resource.memory-mb

Defines how much memory a node controlled by a node manager is allowed to allocate. This setting should be set to amount of which OS is able give to YARN managed processes in a way which doesn't cause OS to swap, etc.

17.8 Configure Kerberos

Enabling kerberos is relatively easy when existing kerberized cluster exists. Just like with every other hadoop related service, use a specific user and a keytab.

```
spring:
  hadoop:
    security:
      userPrincipal: scdf/_HOST@HORTONWORKS.COM
      userKeytab: /etc/security/keytabs/scdf.service.keytab
      authMethod: kerberos
      namenodePrincipal: nn/_HOST@HORTONWORKS.COM
      rmManagerPrincipal: rm/_HOST@HORTONWORKS.COM
      jobHistoryPrincipal: jhs/_HOST@HORTONWORKS.COM
```

Note

When using ambari, configuration and keytab generation are fully automated.

Working with Kerberized Kafka

Important

Currently released kafka based apps doesn't work with cluster where zookeeper and kafka itself are configured to for kerberos authentication. Workaround is to use rabbit based apps or build stream apps based on new kafka binder having support for kerberized kafka.

After a kafka based stream app has a kerberos support, some settings in ambari's kafka configuration needs to be changed. Effectively `listeners` and `security.inter.broker.protocol` needs to

use `SASL_PLAINTEXT`. Also binder needs to be able to create topics, thus `scdf` user needs to be added to a kafka's super users.

```
listeners=SASL_PLAINTEXT://localhost:6667
security.inter.broker.protocol=SASL_PLAINTEXT
super.users=user:kafka;user:scdf
```

Additional configs are needed for binder and sasl config.

```
spring:
  cloud:
    stream:
      kafka:
        binder:
          configuration:
            security:
              protocol: SASL_PLAINTEXT
spring:
  cloud:
    deployer:
      yarn:
        app:
          streamcontainer:
            saslConfig: "-Djava.security.auth.login.config=/etc/scdf/conf/scdf_kafka_jaas.conf"
```

Where `scdf_kafka_jaas.conf` looks something like shown below.

```
KafkaClient {
  com.sun.security.auth.module.Krb5LoginModule required
  useKeyTab=true
  keyTab="/etc/security/keytabs/scdf.service.keytab"
  storeKey=true
  useTicketCache=false
  serviceName="kafka"
  principal="scdf/sandbox.hortonworks.com@HORTONWORKS.COM";
};
```

Important

When ambari is kerberized via its wizard, everything else is automatically configured except kafka settings for a `super.users`, `listeners` and `security.inter.broker.protocol`.

17.9 Configure Hdfs HA

Generic settings for dataflow components to work with HA setup can be seen below where `id` is set to `mycluster`.

```
spring:
  hadoop:
    fsUri: hdfs://mycluster:8020
    config:
      dfs.ha.automatic-failover.enabled=True
      dfs.nameservices=mycluster

  dfs.client.failover.proxy.provider.mycluster=org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverProxyProvider
  dfs.ha.namenodes.mycluster=nn1,nn2
  dfs.namenode.rpc-address.mycluster.nn2=ambari-3.localdomain:8020
  dfs.namenode.rpc-address.mycluster.nn1=ambari-2.localdomain:8020
```

Note

When using ambari and Hdfs HA setup, configuration is fully automated.

17.10 Configure Database

On default a dataflow server will start embedded H2 database using in-memory storage and effectively using configuration.

```
spring:
  datasource:
    url: jdbc:h2:tcp://localhost:19092/mem:dataflow
    username: sa
    password:
    driverClassName: org.h2.Driver
```

Distribution package contains a bundled self-contained H2 executable which can be used instead. This allows to persist data throughout server restarts and is not limited to single host.

```
./bin/dataflow-server-yarn-h2 --dataflow.database.h2.directory=/var/run/scdf/data
```

```
spring:
  datasource:
    url: jdbc:h2:tcp://neo:19092/dataflow
    username: sa
    password:
    driverClassName: org.h2.Driver
```

Important

With external H2 instance you cannot use `localhost`, instead use a real hostname.

Note

Port can be changed using property `dataflow.database.h2.port`.

This bundled H2 database is also used in ambari to have a default out of a box functionality. Any database supported by a dataflow itself can be used by changing `datasource` settings.

17.11 Configure Network Discovery

YARN Deployer has to be able to talk with *Application Master* which then is responsible controlling containers running stream and task applications. The way this work is that *Application Master* tries to discover its own address which *YARN Deployer* is then able to use. If *YARN* cluster nodes have multiple *NICs* or for some other reason address is discovered wrongly, some settings can be changed to alter default discovery logic.

Below is a generic settings what can be changed.

```
spring
  yarn:
    hostdiscovery:
      pointToPoint: false
      loopback: false
      preferInterface: ['eth', 'en']
      matchIpv4: 192.168.0.0/24
      matchInterface: eth\\d*
```

- **pointToPoint** - Skips all interfaces which are most likely i.e. VPNs. Defaults to *false*.
- **loopback** - Don't take loopback interface. Defaults to *false*.
- **preferInterface** - In case multiple interface names exist, setup preference order for discovery. Format is interface name without number qualifier so with *eth0*, use *eth*. There's no defaults.

- **matchIpv4** - Interface can be matched using its existing ip address which is given as *CIDR* format. There's no defaults.
- **matchInterface** - Interface can also matched using a simple regex pattern which gives even better control if complex interface combinations exist in a cluster. There's no defaults.

18. How YARN Deployment Works

When YARN application is deployed into a YARN cluster it consists of two parts, *Application Master* and *Containers*. Application master is a control program responsible of handling applications lifecycle and allocation of containers. Containers are then where a real heavy lifting is done. In case of a stream there is always minimum of 3 containers, one for application master, one for sink and one for source. When running tasks there is always one application master and one container running a particular task.

Needed application files are pushed into hdfs automatically when needed. After stream and task is used once hdfs directory structure would like like shown above.

```
/dataflow/apps
/dataflow/apps/stream
/dataflow/apps/stream/app
/dataflow/apps/stream/app/application.properties
/dataflow/apps/stream/app/servers.yml
/dataflow/apps/stream/app/spring-cloud-deployer-yarn-appdeployerappmaster-1.0.0.BUILD-SNAPSHOT.jar
/dataflow/apps/task
/dataflow/apps/task/app
/dataflow/apps/task/app/application.properties
/dataflow/apps/task/app/servers.yml
/dataflow/apps/task/app/spring-cloud-deployer-yarn-tasklauncherappmaster-1.0.0.BUILD-SNAPSHOT.jar
```

Note

`/dataflow/apps` can be deleted in case application version is changed or configuration related to `servers.yml` is modified. Once created these files are not overridden.

Application artifacts are cached under `/dataflow/artifacts/cache` directory.

```
/dataflow/artifacts
/dataflow/artifacts/cache
/dataflow/artifacts/cache/hdfs-sink-rabbit-1.0.0.RC1.jar
/dataflow/artifacts/cache/time-source-rabbit-1.0.0.RC1.jar
/dataflow/artifacts/cache/timestamp-task-1.0.0.RC1.jar
```

Important

Artifact caching is happening on two levels, firstly on a local disk where server is running, and secondly in a hdfs cache directory. If working with snapshots or own development, it may be required to wipe out `/dataflow/artifacts/cache` directory and do a server restart.

19. Troubleshooting

YARN is fantastic runtime environment for running various workflows but when things don't work exactly as it was planned, it may be a little bit of a tedious process to find out what went wrong. This section tries to provide instructions how to troubleshoot various issues causing abnormal behaviour.

When something is about to get launched into yarn, a generic procedure goes like this:

- Client is requesting resources(cpu and memory) for an application master.
- Application master is started as an jvm process controlling lifecycle of a yarn application as whole.
- Application master is requesting resources(cpu and memory) for its containers where real work is executed.
- Containers are executed as a jvm processes.

There are various places where things can go wrong in this flow:

- YARN resource scheduler will not allocate resources for a container possibly due to overallocation or misconfiguration.
- YARN will kill container because it thinks that a container is abusing requested amount of memory.
- JVM process itself dies either by abnormal behaviour or OOM errors caused by a wrong jvm options.

Log files are the most obvious place to look errors. YARN application itself writes log files name `Appmaster.stdout`, `Appmaster.stderr`, `Container.stdout` and `Container.stderr` under yarn's application logging directory. Also yarn's own logs for *Resource Manager* and especially for *Node Manager* contains additional information when i.e. containers are getting killed by yarn itself.

20. Using Sandboxes

Sandboxes are a single VM images to ease testing and demos without going through a full multi-machine cluster setup. However these images have a natural restrictions of resources which are a cornerstone of YARN to be able to run applications on it. With same limitations and a carefull configuration it is possible to install Spring Cloud Data Flow on those sandboxes. In this section we try to provide some instructions how this can be accomplished.

20.1 Hortonworks Sandbox

Install plugin repository.

```
$ wget -nv http://repo.spring.io/yum-release-local/scdf/1.2.1/scdf-release-1.2.1.repo -O /etc/yum.repos.d/scdf-release-1.2.1.repo
```

Install plugin.

```
$ ambari-server stop
$ yum -y install scdf-plugin-hdp
$ ambari-server start
```

Add needed services together spring *Spring Cloud Data Flow*. Tune server jvm options. Spring Cloud Data Flow → Configs → Advanced scdf-server-env → scdf-server-env template:

```
export JAVA_OPTS="-Xms512m -Xmx512m"
```

Tune jvm options for application masters and container. Spring Cloud Data Flow → Configs → Custom scdf-site:

```
spring.cloud.deployer.yarn.app.streamappmaster.javaOpts=-Xms512m -Xmx512m
spring.cloud.deployer.yarn.app.streamcontainer.javaOpts=-Xms512m -Xmx512m
spring.cloud.deployer.yarn.app.taskappmaster.javaOpts=-Xms512m -Xmx512m
spring.cloud.deployer.yarn.app.taskcontainer.javaOpts=-Xms512m -Xmx512m
```

Part V. Streams

In this section you will learn all about Streams and how to use them with Spring Cloud Data Flow.

21. Introduction

In Spring Cloud Data Flow, a basic stream defines the ingestion of event data from a *source* to a *sink* that passes through any number of *processors*. Streams are composed of [Spring Cloud Stream](#) applications and the deployment of stream definitions is done via the Data Flow Server (REST API). The [Getting Started](#) section shows you how to start the server and how to start and use the Spring Cloud Data Flow shell.

A high level DSL is used to create stream definitions. The DSL to define a stream that has an http source and a file sink (with no processors) is shown below

```
http | file
```

The DSL mimics UNIX pipes and filters syntax. Default values for ports and filenames are used in this example but can be overridden using `--` options, such as

```
http --server.port=8091 | file --directory=/tmp/httpdata/
```

To create these stream definitions you use the shell or make an HTTP POST request to the Spring Cloud Data Flow Server. For more information on making HTTP request directly to the server, consult the [REST API Guide](#).

22. Stream DSL

In the example above, we connected a source to a sink using the pipe symbol `|`. You can also pass properties to the source and sink configurations. The property names will depend on the individual app implementations, but as an example, the `http` source app exposes a `server.port` setting and it allows you to change the data ingestion port from the default value. To create the stream using port 8000, we would use

```
dataflow:> stream create --definition "http --server.port=8000 | log" --name myhttpstream
```

The shell provides tab completion for application properties and also the shell command `app info <appType> : <appName>` provides additional documentation for all the supported properties.

Note

Supported Stream `<appType>`'s are: source, processor, and sink

23. Register a Stream App

Register a Stream App with the App Registry using the Spring Cloud Data Flow Shell `app register` command. You must provide a unique name, application type, and a URI that can be resolved to the app artifact. For the type, specify "source", "processor", or "sink". Here are a few examples:

```
dataflow:>app register --name mysource --type source --uri maven://com.example:mysource:0.0.1-SNAPSHOT

dataflow:>app register --name myprocessor --type processor --uri file:///Users/example/
myprocessor-1.2.3.jar

dataflow:>app register --name mysink --type sink --uri http://example.com/mysink-2.0.1.jar
```

When providing a URI with the `maven` scheme, the format should conform to the following:

```
maven://<groupId>:<artifactId>[:<extension>[:<classifier>]]:<version>
```

For example, if you would like to register the snapshot versions of the `http` and `log` applications built with the RabbitMQ binder, you could do the following:

```
dataflow:>app register --name http --type source --uri maven://
org.springframework.cloud.stream.app:http-source-rabbit:1.2.1.BUILD-SNAPSHOT
dataflow:>app register --name log --type sink --uri maven://org.springframework.cloud.stream.app:log-
sink-rabbit:1.2.1.BUILD-SNAPSHOT
```

If you would like to register multiple apps at one time, you can store them in a properties file where the keys are formatted as `<type>.<name>` and the values are the URIs.

For example, if you would like to register the snapshot versions of the `http` and `log` applications built with the RabbitMQ binder, you could have the following in a properties file [eg: *stream-apps.properties*]:

```
source.http=maven://org.springframework.cloud.stream.app:http-source-rabbit:1.2.1.BUILD-SNAPSHOT
sink.log=maven://org.springframework.cloud.stream.app:log-sink-rabbit:1.2.1.BUILD-SNAPSHOT
```

Then to import the apps in bulk, use the `app import` command and provide the location of the properties file via `--uri`:

```
dataflow:>app import --uri file:///<YOUR_FILE_LOCATION>/stream-apps.properties
```

For convenience, we have the static files with application-URIs (for both maven and docker) available for all the out-of-the-box stream and task/batch app-starters. You can point to this file and import all the application-URIs in bulk. Otherwise, as explained in previous paragraphs, you can register them individually or have your own custom property file with only the required application-URIs in it. It is recommended, however, to have a "focused" list of desired application-URIs in a custom property file.

List of available Stream Application Starters:

Artifact Type	Stable Release	SNAPSHOT Release
RabbitMQ + Maven	bit.ly/Bacon-RELEASE-stream-applications-rabbit-maven	bit.ly/Bacon-BUILD-SNAPSHOT-stream-applications-rabbit-maven
RabbitMQ + Docker	bit.ly/Bacon-RELEASE-stream-applications-rabbit-docker	N/A

Artifact Type	Stable Release	SNAPSHOT Release
Kafka 0.9 + Maven	bit.ly/Bacon-RELEASE-stream-applications-kafka-09-maven	bit.ly/Bacon-BUILD-SNAPSHOT-stream-applications-kafka-09-maven
Kafka 0.9 + Docker	bit.ly/Bacon-RELEASE-stream-applications-kafka-09-docker	N/A
Kafka 0.10 + Maven	bit.ly/Bacon-RELEASE-stream-applications-kafka-10-maven	bit.ly/Bacon-BUILD-SNAPSHOT-stream-applications-kafka-10-maven
Kafka 0.10 + Docker	bit.ly/Bacon-RELEASE-stream-applications-kafka-10-docker	N/A

List of available Task Application Starters:

Artifact Type	Stable Release	SNAPSHOT Release
Maven	bit.ly/Belmont-GA-task-applications-maven	bit.ly/Belmont-BUILD-SNAPSHOT-task-applications-maven
Docker	bit.ly/Belmont-GA-task-applications-docker	N/A

You can find more information about the available task starters in the [Task App Starters Project Page](#) and related reference documentation. For more information about the available stream starters look at the [Stream App Starters Project Page](#) and related reference documentation.

As an example, if you would like to register all out-of-the-box stream applications built with the RabbitMQ binder in bulk, you can with the following command.

```
dataflow:>app import --uri http://bit.ly/Bacon-RELEASE-stream-applications-rabbit-maven
```

You can also pass the `--local` option (which is `true` by default) to indicate whether the properties file location should be resolved within the shell process itself. If the location should be resolved from the Data Flow Server process, specify `--local false`.

Warning

When using either `app register` or `app import`, if an app is already registered with the provided name and type, it will not be overridden by default. If you would like to override the pre-existing app coordinates, then include the `--force` option.

Note however that once downloaded, applications may be cached locally on the Data Flow server, based on the resource location. If the resource location doesn't change (even though the actual resource *bytes* may be different), then it won't be re-downloaded. When using `maven://resources` on the other hand, using a constant location still may circumvent caching (if using `-SNAPSHOT` versions).

Moreover, if a stream is already deployed and using some version of a registered app, then (forcibly) re-registering a different app will have no effect until the stream is deployed anew.

**Note**

In some cases the Resource is resolved on the server side, whereas in others the URI will be passed to a runtime container instance where it is resolved. Consult the specific documentation of each Data Flow Server for more detail.

23.1 Whitelisting application properties

Stream and Task applications are Spring Boot applications which are aware of many [Section 25.3, “Common application properties”](#), e.g. `server.port` but also families of properties such as those with the prefix `spring.jmx` and `logging`. When creating your own application it is desirable to whitelist properties so that the shell and the UI can display them first as primary properties when presenting options via TAB completion or in drop-down boxes.

To whitelist application properties create a file named `spring-configuration-metadata-whitelist.properties` in the `META-INF` resource directory. There are two property keys that can be used inside this file. The first key is named `configuration-properties.classes`. The value is a comma separated list of fully qualified `@ConfigurationProperty` class names. The second key is `configuration-properties.names` whose value is a comma separated list of property names. This can contain the full name of property, such as `server.port` or a partial name to whitelist a category of property names, e.g. `spring.jmx`.

The [Spring Cloud Stream application starters](#) are a good place to look for examples of usage. Here is a simple example of the file sink's `spring-configuration-metadata-whitelist.properties` file

```
configuration-properties.classes=org.springframework.cloud.stream.app.file.sink.FileSinkProperties
```

If we also wanted to add `server.port` to be white listed, then it would look like this:

```
configuration-properties.classes=org.springframework.cloud.stream.app.file.sink.FileSinkProperties
configuration-properties.names=server.port
```

**Important**

Make sure to add 'spring-boot-configuration-processor' as an optional dependency to generate configuration metadata file for the properties.

```
<dependency>
  <groupId>org.springframework.boot</groupId>
  <artifactId>spring-boot-configuration-processor</artifactId>
  <optional>true</optional>
</dependency>
```

23.2 Creating and using a dedicated metadata artifact

You can go a step further in the process of describing the main properties that your stream or task app supports by creating a so-called metadata companion artifact. This simple jar file contains only the Spring boot JSON file about configuration properties metadata, as well as the whitelisting file described in the previous section.

Here is the contents of such an artifact, for the canonical `log` sink:

```
$ jar tvf log-sink-rabbit-1.2.1.BUILD-SNAPSHOT-metadata.jar
373848 META-INF/spring-configuration-metadata.json
```

174 META-INF/spring-configuration-metadata-whitelist.properties

Note that the `spring-configuration-metadata.json` file is quite large. This is because it contains the concatenation of *all* the properties that are available at runtime to the log sink (some of them come from `spring-boot-actuator.jar`, some of them come from `spring-boot-autoconfigure.jar`, even some more from `spring-cloud-starter-stream-sink-log.jar`, etc.) Data Flow always relies on all those properties, even when a companion artifact is not available, but here all have been merged into a single file.

To help with that (as a matter of fact, you don't want to try to craft this giant JSON file by hand), you can use the following plugin in your build:

```
<plugin>
  <groupId>org.springframework.cloud</groupId>
  <artifactId>spring-cloud-app-starter-metadata-maven-plugin</artifactId>
  <executions>
    <execution>
      <id>aggregate-metadata</id>
      <phase>compile</phase>
      <goals>
        <goal>aggregate-metadata</goal>
      </goals>
    </execution>
  </executions>
</plugin>
```

Note

This plugin comes in *addition* to the `spring-boot-configuration-processor` that creates the individual JSON files. Be sure to configure the two!

The benefits of a companion artifact are manifold:

1. being way lighter (usually a few kilobytes, as opposed to megabytes for the actual app), they are quicker to download, allowing quicker feedback when using e.g. `app info` or the Dashboard UI
2. as a consequence of the above, they can be used in resource constrained environments (such as PaaS) when metadata is the only piece of information needed
3. finally, for environments that don't deal with boot uberjars directly (for example, Docker-based runtimes such as Kubernetes or Mesos), this is the only way to provide metadata about the properties supported by the app.

Remember though, that this is entirely optional when dealing with uberjars. The uberjar itself *also* includes the metadata in it already.

Using the companion artifact

Once you have a companion artifact at hand, you need to make the system aware of it so that it can be used.

When registering a single app *via* `app register`, you can use the optional `--metadata-uri` option in the shell, like so:

```
dataflow:>app register --name log --type sink
--uri maven://org.springframework.cloud.stream.app:log-sink-kafka-10:1.2.1.BUILD-SNAPSHOT
--metadata-uri=maven://org.springframework.cloud.stream.app:log-sink-
kafka-10:jar:metadata:1.2.1.BUILD-SNAPSHOT
```

When registering several files using the `app import` command, the file should contain a `<type>.<name>.metadata` line in addition to each `<type>.<name>` line. This is optional (*i.e.* if some apps have it but some others don't, that's fine).

Here is an example for a Dockerized app, where the metadata artifact is being hosted in a Maven repository (but retrieving it *via* `http://` or `file://` would be equally possible).

```
...
source.http=docker:springcloudstream/http-source-rabbit:latest
source.http.metadata=maven://org.springframework.cloud.stream.app:http-source-
rabbit:jar:metadata:1.2.1.BUILD-SNAPSHOT
...
```

24. Creating custom applications

While there are out of the box source, processor, sink applications available, one can extend these applications or write a custom [Spring Cloud Stream](#) application.

The process of creating Spring Cloud Stream applications via Spring Initializr is detailed in the [Spring Cloud Stream 1.2.1.RELEASE#_getting_started\[documentation\]](#). It is possible to include multiple binders to an application. If doing so, refer the instructions in [the section called “Passing Spring Cloud Stream properties for the application”](#) on how to configure them.

For supporting property whitelisting, Spring Cloud Stream applications running in Spring Cloud Data Flow may include the Spring Boot `configuration-processor` as an optional dependency, as in the following example.

```
<dependencies>
<!-- other dependencies -->
<dependency>
  <groupId>org.springframework.boot</groupId>
  <artifactId>spring-boot-configuration-processor</artifactId>
  <optional>true</optional>
</dependency>
</dependencies>
```

Note

Make sure that the `spring-boot-maven-plugin` is included in the POM. The plugin is necessary for creating the executable jar that will be registered with Spring Cloud Data Flow. Spring Initializr will include the plugin in the generated POM.

Once a custom application has been created, it can be registered as described in [Chapter 23, Register a Stream App](#).

25. Creating a Stream

The Spring Cloud Data Flow Server exposes a full RESTful API for managing the lifecycle of stream definitions, but the easiest way to use it is via the Spring Cloud Data Flow shell. Start the shell as described in the [Getting Started](#) section.

New streams are created by with the help of stream definitions. The definitions are built from a simple DSL. For example, let's walk through what happens if we execute the following shell command:

```
dataflow:> stream create --definition "time | log" --name ticktock
```

This defines a stream named `ticktock` based off the DSL expression `time | log`. The DSL uses the "pipe" symbol `|`, to connect a source to a sink.

Then to deploy the stream execute the following shell command (or alternatively add the `--deploy` flag when creating the stream so that this step is not needed):

```
dataflow:> stream deploy --name ticktock
```

The Data Flow Server resolves `time` and `log` to maven coordinates and uses those to launch the `time` and `log` applications of the stream.

```
2016-06-01 09:41:21.728 INFO 79016 --- [nio-9393-exec-6] o.s.c.d.spi.local.LocalAppDeployer :
  deploying app ticktock.log instance 0
  Logs will be in /var/folders/wn/8jxm_tbdlvj28c8vj37n900m0000gn/T/spring-cloud-
dataflow-912434582726479179/ticktock-1464788481708/ticktock.log
2016-06-01 09:41:21.914 INFO 79016 --- [nio-9393-exec-6] o.s.c.d.spi.local.LocalAppDeployer :
  deploying app ticktock.time instance 0
  Logs will be in /var/folders/wn/8jxm_tbdlvj28c8vj37n900m0000gn/T/spring-cloud-
dataflow-912434582726479179/ticktock-1464788481910/ticktock.time
```

In this example, the `time` source simply sends the current time as a message each second, and the `log` sink outputs it using the logging framework. You can tail the `stdout` log (which has an "`_instance>`" suffix). The log files are located within the directory displayed in the Data Flow Server's log output, as shown above.

```
$ tail -f /var/folders/wn/8jxm_tbdlvj28c8vj37n900m0000gn/T/spring-cloud-dataflow-912434582726479179/
ticktock-1464788481708/ticktock.log/stdout_0.log
2016-06-01 09:45:11.250 INFO 79194 --- [ kafka-binder-] log.sink : 06/01/16 09:45:11
2016-06-01 09:45:12.250 INFO 79194 --- [ kafka-binder-] log.sink : 06/01/16 09:45:12

```

25.1 Application properties

Application properties are the properties associated with each application in the stream. When the application is deployed, the application properties are applied to the application via command line arguments or environment variables based on the underlying deployment implementation.

Passing application properties when creating a stream

The following stream

```
dataflow:> stream create --definition "time | log" --name ticktock
```

can have application properties defined at the time of stream creation.

The shell command `app info <appType>:<appName>` displays the white-listed application properties for the application. For more info on the property white listing refer to [Section 23.1, “Whitelisting application properties”](#)

Below are the white listed properties for the app `time`:

```
dataflow:> app info source:time
#####
#      Option Name      #      Description      #      Default      #
#      Type              #
#####
#trigger.time-unit      #The TimeUnit to apply to delay#<none>
#java.util.concurrent.TimeUnit #
#      #                  #values.                  #
#      #                  #
#trigger.fixed-delay    #Fixed delay for periodic    #1
#java.lang.Integer      #
#      #                  #triggers.                  #
#      #                  #
#trigger.cron           #Cron expression value for the #<none>
#java.lang.String       #
#      #                  #Cron Trigger.            #
#      #                  #
#trigger.initial-delay  #Initial delay for periodic  #0
#java.lang.Integer      #
#      #                  #triggers.                  #
#      #                  #
#trigger.max-messages   #Maximum messages per poll, -1 #1
#java.lang.Long         #
#      #                  #means infinity.          #
#      #                  #
#trigger.date-format    #Format for the date value.  #<none>
#java.lang.String       #
#####
```

Below are the white listed properties for the app `log`:

```
dataflow:> app info sink:log
#####
#      Option Name      #      Description      #      Default      #
#      Type              #
#####
#log.name               #The name of the logger to use.#<none>
#java.lang.String       #
#log.level              #The level at which to log    #<none>
#org.springframework.integration#
#      #                  #messages.                  #
#      #                  #
#n.handler.LoggingHandler$Level#
#log.expression         #A SpEL expression (against the#payload
#java.lang.String       #
#      #                  #incoming message) to evaluate #
#      #                  #
#      #                  #as the logged message.    #
#      #                  #
#####
```

The application properties for the `time` and `log` apps can be specified at the time of stream creation as follows:

```
dataflow:> stream create --definition "time --fixed-delay=5 / log --level=WARN" --name ticktock
```

Note that the properties `fixed-delay` and `level` defined above for the apps `time` and `log` are the 'short-form' property names provided by the shell completion. These 'short-form' property names are applicable only for the white-listed properties and in all other cases, only *fully qualified* property names should be used.

25.2 Deployment properties

When deploying the stream, properties that control the deployment of the apps into the target platform are known as `deployment` properties. For instance, one can specify how many instances need to be deployed for the specific application defined in the stream using the deployment property called `count`.

Application properties versus Deployer properties

Starting with version 1.2, the distinction between properties that are meant for the *deployed app* and properties that govern *how* this app is deployed (thanks to some implementation of a [spring cloud deployer](#)) is more explicit. The former should be passed using the syntax `app.<app-name>.<property-name>=<value>` while the latter use the `deployer.<app-name>.<short-property-name>=<value>`

The following table recaps the difference in behavior between the two.

	Application Properties	Deployer Properties
Example Syntax	<code>app.filter.expression=foo</code>	<code>deployer.filter.count=3</code>
What the application "sees"	<code>expression=foo</code> or <code><some-prefix>.expression=foo</code> if <code>expression</code> is one of the whitelisted properties	Nothing
What the deployer "sees"	Nothing	<code>spring.cloud.deployer.count=3</code> The <code>spring.cloud.deployer</code> prefix is automatically and always prepended to the property name
Typical usage	Passing/Overriding application properties, passing Spring Cloud Stream binder or partitioning properties	Setting the number of instances, memory, disk, etc.

Passing instance count as deployment property

If you would like to have multiple instances of an application in the stream, you can include a deployer property with the `deploy` command:

```
dataflow:> stream deploy --name ticktock --properties "deployer.time.count=3"
```

Note that `count` is the **reserved** property name used by the underlying deployer. Hence, if the application also has a custom property named `count`, it is **not** supported when specified in 'short-form' form during stream *deployment* as it could conflict with the *instance* count deployer property. Instead, the `count` as a custom application property can be specified in its *fully qualified* form (example: `app.foo.bar.count`) during stream *deployment* or it can be specified using 'short-form' or *fully qualified* form during the stream *creation* where it will be considered as an app property.

Important

See [Chapter 32, Using Labels in a Stream](#).

Inline vs file reference properties

When using the Spring Cloud Data Flow Shell, there are two ways to provide deployment properties: either **inline** or via a **file reference**. Those two ways are exclusive and documented below:

Inline properties

use the `--properties` shell option and list properties as a comma separated list of key=value pairs, like so:

```
stream deploy foo
  --properties "deployer.transform.count=2,app.transform.producer.partitionKeyExpression=payload"
```

Using a file reference

use the `--propertiesFile` option and point it to a local `.properties`, `.yaml` or `.yml` file (i.e. that lives in the filesystem of the machine running the shell). Being read as a `.properties` file, normal rules apply (ISO 8859-1 encoding, `=`, `<space>` or `:` delimiter, etc.) although we recommend using `=` as a key-value pair delimiter for consistency:

```
stream deploy foo --propertiesFile myprops.properties
```

where `myprops.properties` contains:

```
deployer.transform.count=2
app.transform.producer.partitionKeyExpression=payload
```

Both the above properties will be passed as deployment properties for the stream `foo` above.

In case of using YAML as the format for the deployment properties, use the `.yaml` or `.yml` file extension when deploying the stream,

```
stream deploy foo --propertiesFile myprops.yaml
```

where `myprops.yaml` contains:

```
deployer:
  transform:
    count: 2
app:
  transform:
    producer:
      partitionKeyExpression: payload
```

Passing application properties when deploying a stream

The application properties can also be specified when deploying a stream. When specified during deployment, these application properties can either be specified as 'short-form' property names (applicable for white-listed properties) or *fully qualified* property names. The application properties should have the prefix `"app.<appName/label>"`.

For example, the stream

```
dataflow:> stream create --definition "time / log" --name ticktock
```

can be deployed with application properties using the 'short-form' property names:

```
dataflow:>stream deploy ticktock --properties "app.time.fixed-delay=5,app.log.level=ERROR"
```

When using the app label,

```
stream create ticktock --definition "a: time / b: log"
```

the application properties can be defined as:

```
stream deploy ticktock --properties "app.a.fixed-delay=4,app.b.level=ERROR"
```

Passing Spring Cloud Stream properties for the application

Spring Cloud Data Flow sets the required Spring Cloud Stream properties for the applications inside the stream. Most importantly, the `spring.cloud.stream.bindings.<input/output>.destination` is set internally for the apps to bind.

If someone wants to override any of the Spring Cloud Stream properties, they can be set via deployment properties.

For example, for the below stream

```
dataflow:> stream create --definition "http / transform --
expression=payload.getValue('hello').toUpperCase() / log" --name ticktock
```

if there are multiple binders available in the classpath for each of the applications and the binder is chosen for each deployment then the stream can be deployed with the specific Spring Cloud Stream properties as:

```
dataflow:>stream deploy ticktock --
properties "app.time.spring.cloud.stream.bindings.output.binder=kafka,app.transform.spring.cloud.stream.bindings.input.binder=kafka"
```

Note

Overriding the destination names is not recommended as Spring Cloud Data Flow takes care of setting this internally.

Passing per-binding producer consumer properties

A Spring Cloud Stream application can have producer and consumer properties set per-binding basis. While Spring Cloud Data Flow supports specifying short-hand notation for per binding producer properties such as `partitionKeyExpression`, `partitionKeyExtractorClass` as described in [the section called “Passing stream partition properties during stream deployment”](#), all the supported Spring Cloud Stream producer/consumer properties can be set as Spring Cloud Stream properties for the app directly as well.

The consumer properties can be set for the inbound channel name with the prefix `app.[app/label name].spring.cloud.stream.bindings.<channelName>.consumer.` and the producer properties can be set for the outbound channel name with the prefix `app.[app/label name].spring.cloud.stream.bindings.<channelName>.producer..` For example, the stream

```
dataflow:> stream create --definition "time / log" --name ticktock
```

can be deployed with producer/consumer properties as:

```
dataflow:>stream deploy ticktock --
properties "app.time.spring.cloud.stream.bindings.output.producer.requiredGroups=myGroup,app.time.spring.cloud.stream.bindings.output.producer.groupId=myGroup"
```

The binder specific producer/consumer properties can also be specified in a similar way.

For instance

```
dataflow:>stream deploy ticktock --
properties "app.time.spring.cloud.stream.rabbit.bindings.output.producer.autoBindDlq=true,app.log.spring.cloud.stream.rabbit"
```

Passing stream partition properties during stream deployment

A common pattern in stream processing is to partition the data as it is streamed. This entails deploying multiple instances of a message consuming app and using content-based routing so that messages with a given key (as determined at runtime) are always routed to the same app instance. You can pass the partition properties during stream deployment to declaratively configure a partitioning strategy to route each message to a specific consumer instance.

See below for examples of deploying partitioned streams:

app.[app/label name].producer.partitionKeyExtractorClass

The class name of a PartitionKeyExtractorStrategy (default `null`)

app.[app/label name].producer.partitionKeyExpression

A SpEL expression, evaluated against the message, to determine the partition key; only applies if `partitionKeyExtractorClass` is null. If both are null, the app is not partitioned (default `null`)

app.[app/label name].producer.partitionSelectorClass

The class name of a PartitionSelectorStrategy (default `null`)

app.[app/label name].producer.partitionSelectorExpression

A SpEL expression, evaluated against the partition key, to determine the partition index to which the message will be routed. The final partition index will be the return value (an integer) modulo `[nextModule].count`. If both the class and expression are null, the underlying binder's default PartitionSelectorStrategy will be applied to the key (default `null`)

In summary, an app is partitioned if its count is `> 1` and the previous app has a `partitionKeyExtractorClass` or `partitionKeyExpression` (class takes precedence). When a partition key is extracted, the partitioned app instance is determined by invoking the `partitionSelectorClass`, if present, or the `partitionSelectorExpression` % `partitionCount`, where `partitionCount` is application count in the case of RabbitMQ, and the underlying partition count of the topic in the case of Kafka.

If neither a `partitionSelectorClass` nor a `partitionSelectorExpression` is present the result is `key.hashCode() % partitionCount`.

Passing application content type properties

In a stream definition you can specify that the input or the output of an application need to be converted to a different type. You can use the `inputType` and `outputType` properties to specify the content type for the incoming data and outgoing data, respectively.

For example, consider the following stream:

```
dataflow:>stream create tuple --definition "http | filter --inputType=application/x-spring-tuple
--expression=payload.hasFieldName('hello') | transform --
expression=payload.getValue('hello').toUpperCase()
| log" --deploy
```

The `http` app is expected to send the data in JSON and the `filter` app receives the JSON data and processes it as a Spring Tuple. In order to do so, we use the `inputType` property on the filter app

to convert the data into the expected Spring Tuple format. The `transform` application processes the Tuple data and sends the processed data to the downstream `log` application.

When sending some data to the `http` application:

```
dataflow:>http post --data {"hello":"world","foo":"bar"} --contentType application/json --target http://localhost:<http-port>
```

At the `log` application you see the content as follows:

```
INFO 18745 --- [transform.tuple-1] log.sink : WORLD
```

Depending on how applications are chained, the content type conversion can be specified either as via the `--outputType` in the upstream app or as an `--inputType` in the downstream app. For instance, in the above stream, instead of specifying the `--inputType` on the 'transform' application to convert, the option `--outputType=application/x-spring-tuple` can also be specified on the 'http' application.

For the complete list of message conversion and message converters, please refer to [Spring Cloud Stream 1.2.1.RELEASE#contenttypemanagement\[documentation\]](#).

Overriding application properties during stream deployment

Application properties that are defined during deployment override the same properties defined during the stream creation.

For example, the following stream has application properties defined during stream creation:

```
dataflow:> stream create --definition "time --fixed-delay=5 / log --level=WARN" --name ticktock
```

To override these application properties, one can specify the new property values during deployment:

```
dataflow:>stream deploy ticktock --properties "app.time.fixed-delay=4,app.log.level=ERROR"
```

25.3 Common application properties

In addition to configuration via DSL, Spring Cloud Data Flow provides a mechanism for setting common properties to all the streaming applications that are launched by it. This can be done by adding properties prefixed with `spring.cloud.dataflow.applicationProperties.stream` when starting the server. When doing so, the server will pass all the properties, without the prefix, to the instances it launches.

For example, all the launched applications can be configured to use a specific Kafka broker by launching the Data Flow server with the following options:

```
--
spring.cloud.dataflow.applicationProperties.stream.spring.cloud.stream.kafka.binder.brokers=192.168.1.100:9092
--
spring.cloud.dataflow.applicationProperties.stream.spring.cloud.stream.kafka.binder.zkNodes=192.168.1.100:2181
```

This will cause the properties `spring.cloud.stream.kafka.binder.brokers` and `spring.cloud.stream.kafka.binder.zkNodes` to be passed to all the launched applications.

Note

Properties configured using this mechanism have lower precedence than stream deployment properties. They will be overridden if a property with the same key is specified at stream

deployment time (e.g. `app.http.spring.cloud.stream.kafka.binder.brokers` will override the common property).

26. Destroying a Stream

You can delete a stream by issuing the `stream destroy` command from the shell:

```
dataflow:> stream destroy --name ticktock
```

If the stream was deployed, it will be undeployed before the stream definition is deleted.

27. Deploying and Undeploying Streams

Often you will want to stop a stream, but retain the name and definition for future use. In that case you can `undeploy` the stream by name and issue the `deploy` command at a later time to restart it.

```
dataflow:> stream undeploy --name ticktock  
dataflow:> stream deploy --name ticktock
```

28. Other Source and Sink Application Types

Let's try something a bit more complicated and swap out the `time` source for something else. Another supported source type is `http`, which accepts data for ingestion over HTTP POSTs. Note that the `http` source accepts data on a different port from the Data Flow Server (default 8080). By default the port is randomly assigned.

To create a stream using an `http` source, but still using the same `log` sink, we would change the original command above to

```
dataflow:> stream create --definition "http | log" --name myhttpstream --deploy
```

which will produce the following output from the server

```
2016-06-01 09:47:58.920 INFO 79016 --- [io-9393-exec-10] o.s.c.d.spi.local.LocalAppDeployer :
    deploying app myhttpstream.log instance 0
    Logs will be in /var/folders/wn/8jxm_tbdlvj28c8vj37n900m0000gn/T/spring-cloud-
dataflow-912434582726479179/myhttpstream-1464788878747/myhttpstream.log
2016-06-01 09:48:06.396 INFO 79016 --- [io-9393-exec-10] o.s.c.d.spi.local.LocalAppDeployer :
    deploying app myhttpstream.http instance 0
    Logs will be in /var/folders/wn/8jxm_tbdlvj28c8vj37n900m0000gn/T/spring-cloud-
dataflow-912434582726479179/myhttpstream-1464788886383/myhttpstream.http
```

Note that we don't see any other output this time until we actually post some data (using a shell command). In order to see the randomly assigned port on which the `http` source is listening, execute:

```
dataflow:> runtime apps
```

You should see that the corresponding `http` source has a `url` property containing the host and port information on which it is listening. You are now ready to post to that url, e.g.:

```
dataflow:> http post --target http://localhost:1234 --data "hello"
dataflow:> http post --target http://localhost:1234 --data "goodbye"
```

and the stream will then funnel the data from the `http` source to the output log implemented by the `log` sink

```
2016-06-01 09:50:22.121 INFO 79654 --- [ kafka-binder-] log.sink : hello
2016-06-01 09:50:26.810 INFO 79654 --- [ kafka-binder-] log.sink : goodbye
```

Of course, we could also change the sink implementation. You could pipe the output to a file (`file`), to `hadoop` (`hdfs`) or to any of the other sink apps which are available. You can also define your own apps.

29. Simple Stream Processing

As an example of a simple processing step, we can transform the payload of the HTTP posted data to upper case using the stream definitions

```
http | transform --expression=payload.toUpperCase() | log
```

To create this stream enter the following command in the shell

```
dataflow:> stream create --definition "http | transform --expression=payload.toUpperCase() | log" --name  
mystream --deploy
```

Posting some data (using a shell command)

```
dataflow:> http post --target http://localhost:1234 --data "hello"
```

Will result in an uppercased 'HELLO' in the log

```
2016-06-01 09:54:37.749 INFO 80083 --- [ kafka-binder-] log.sink : HELLO
```

30. Stateful Stream Processing

To demonstrate the data partitioning functionality, let's deploy the following stream with Kafka as the binder.

```
dataflow:>stream create --name words --definition "http --server.port=9900 | splitter --
expression=payload.split(' ') | log"
Created new stream 'words'

dataflow:>stream deploy words --properties
"app.splitter.producer.partitionKeyExpression=payload,deployer.log.count=2"
Deployed stream 'words'

dataflow:>http post --target http://localhost:9900 --data "How much wood would a woodchuck chuck if a
woodchuck could chuck wood"
> POST (text/plain;Charset=UTF-8) http://localhost:9900 How much wood would a woodchuck chuck if a
woodchuck could chuck wood
> 202 ACCEPTED
```

You'll see the following in the server logs.

```
2016-06-05 18:33:24.982 INFO 58039 --- [nio-9393-exec-9] o.s.c.d.spi.local.LocalAppDeployer :
deploying app words.log instance 0

2016-06-05 18:35:47.066 INFO 58639 --- [ kafka-binder-] log.sink : a
2016-06-05 18:35:47.066 INFO 58639 --- [ kafka-binder-] log.sink :
woodchuck
2016-06-05 18:35:47.067 INFO 58639 --- [ kafka-binder-] log.sink : if
2016-06-05 18:35:47.067 INFO 58639 --- [ kafka-binder-] log.sink : a
2016-06-05 18:35:47.067 INFO 58639 --- [ kafka-binder-] log.sink :
woodchuck
2016-06-05 18:35:47.067 INFO 58639 --- [ kafka-binder-] log.sink :
could
2016-06-05 18:35:47.067 INFO 58639 --- [ kafka-binder-] log.sink :
wood
```

This shows that payload splits that contain the same word are routed to the same application instance.

31. Tap a Stream

Taps can be created at various producer endpoints in a stream. For a stream like this:

```
stream create --definition "http | step1: transform --expression=payload.toUpperCase() | step2:
transform --expression=payload+'!' | log" --name mainstream --deploy
```

taps can be created at the output of `http`, `step1` and `step2`.

To create a stream that acts as a 'tap' on another stream requires to specify the `source destination name` for the tap stream. The syntax for source destination name is:

```
`:<streamName>.<label/appName>`
```

To create a tap at the output of `http` in the stream above, the source destination name is `mainstream.http` To create a tap at the output of the first transform app in the stream above, the source destination name is `mainstream.step1`

The tap stream DSL looks like this:

```
stream create --definition ":mainstream.http > counter" --name tap_at_http --deploy

stream create --definition ":mainstream.step1 > jdbc" --name tap_at_step1_transformer --deploy
```

Note the colon (:) prefix before the destination names. The colon allows the parser to recognize this as a destination name instead of an app name.

32. Using Labels in a Stream

When a stream is comprised of multiple apps with the same name, they must be qualified with labels:

```
stream create --definition "http | firstLabel: transform --expression=payload.toUpperCase() |  
secondLabel: transform --expression=payload+'!' | log" --name myStreamWithLabels --deploy
```

33. Explicit Broker Destinations in a Stream

One can connect to a specific destination name located in the broker (Rabbit, Kafka etc.,) either at the `source` or at the `sink` position.

The following stream has the destination name at the `source` position:

```
stream create --definition ":myDestination > log" --name ingest_from_broker --deploy
```

This stream receives messages from the destination `myDestination` located at the broker and connects it to the `log` app.

The following stream has the destination name at the `sink` position:

```
stream create --definition "http > :myDestination" --name ingest_to_broker --deploy
```

This stream sends the messages from the `http` app to the destination `myDestination` located at the broker.

From the above streams, notice that the `http` and `log` apps are interacting with each other via the broker (through the destination `myDestination`) rather than having a pipe directly between `http` and `log` within a single stream.

It is also possible to connect two different destinations (`source` and `sink` positions) at the broker in a stream.

```
stream create --definition ":destination1 > :destination2" --name bridge_destinations --deploy
```

In the above stream, both the destinations (`destination1` and `destination2`) are located in the broker. The messages flow from the source destination to the sink destination via a `bridge` app that connects them.

34. Directed Graphs in a Stream

If directed graphs are needed instead of the simple linear streams described above, two features are relevant.

First, named destinations may be used as a way to combine the output from multiple streams or for multiple consumers to share the output from a single stream. This can be done using the DSL syntax `http > :mydestination` or `:mydestination > log`.

Second, you may need to determine the output channel of a stream based on some information that is only known at runtime. In that case, a router may be used in the sink position of a stream definition. For more information, refer to the Router Sink starter's [README](#).

35. Stream applications with multiple binder configurations

In some cases, a stream can have its applications bound to multiple spring cloud stream binders when they are required to connect to different messaging middleware configurations. In those cases, it is important to make sure the applications are configured appropriately with their binder configurations. For example, let's consider the following stream:

```
http | transform --expression=payload.toUpperCase() | log
```

and in this stream, each application connects to messaging middleware in the following way:

```
Http source sends events to RabbitMQ (rabbit1)
Transform processor receives events from RabbitMQ (rabbit1) and sends the processed events into Kafka
(kafkal)
Log sink receives events from Kafka (kafkal)
```

Here, `rabbit1` and `kafkal` are the binder names given in the spring cloud stream application properties. Based on this setup, the applications will have the following binder(s) in their classpath with the appropriate configuration:

```
Http - Rabbit binder
Transform - Both Kafka and Rabbit binders
Log - Kafka binder
```

The `spring-cloud-stream` binder configuration properties can be set within the applications themselves. If not, they can be passed via deployment properties when the stream is deployed.

For example,

```
dataflow:>stream create --definition "http | transform --expression=payload.toUpperCase() | log" --name
mystream
```

```
dataflow:>stream deploy mystream --properties
"app.http.spring.cloud.stream.bindings.output.binder=rabbit1,app.transform.spring.cloud.stream.bindings.input.binder=rabbit1,
app.transform.spring.cloud.stream.bindings.output.binder=kafkal,app.log.spring.cloud.stream.bindings.input.binder=kafkal"
```

One can override any of the binder configuration properties by specifying them via deployment properties.

Part VI. Tasks

This section goes into more detail about how you can work with [Spring Cloud Task](#). It covers topics such as creating and running task applications.

If you're just starting out with Spring Cloud Data Flow, you should probably read the [Getting Started](#) guide before diving into this section.

36. Introducing Spring Cloud Task

A task executes a process on demand. In this case a task is a [Spring Boot](#) application that is annotated with `@EnableTask`. Hence a user launches a task that performs a certain process, and once complete the task ends. An example of a task would be a boot application that exports data from a JDBC repository to an HDFS instance. Tasks record the start time and the end time as well as the boot exit code in a relational database. The task implementation is based on the [Spring Cloud Task](#) project.

37. The Lifecycle of a task

Before we dive deeper into the details of creating Tasks, we need to understand the typical lifecycle for tasks in the context of Spring Cloud Data Flow:

1. Register a Task App
2. Create a Task Definition
3. Launch a Task
4. Task Execution
5. Destroy a Task Definition

37.1 Creating a custom Task Application

While Spring Cloud Task does provide a number of out of the box applications (via the [spring-cloud-task-app-starters](#)), most task applications will be custom developed. In order to create a custom task application:

1. Create a new project via [Spring Initializer](#) via either the website or your IDE making sure to select the following starters:
 - a. Cloud Task - This dependency is the `spring-cloud-starter-task`.
 - b. JDBC - This is the dependency for the `spring-jdbc` starter.
2. Within your new project, create a new class that will serve as your main class:

```
@EnableTask
@SpringBootApplication
public class MyTask {

    public static void main(String[] args) {
        SpringApplication.run(MyTask.class, args);
    }
}
```

3. With this, you'll need one or more `CommandLineRunner` or `ApplicationRunner` within your application. You can either implement your own or use the ones provided by Spring Boot (there is one for running batch jobs for example).
4. Packaging your application up via Spring Boot into an über jar is done via the standard Boot conventions.
5. The packaged application can be registered and deployed as noted below.

37.2 Registering a Task Application

Register a Task App with the App Registry using the Spring Cloud Data Flow Shell `app register` command. You must provide a unique name and a URI that can be resolved to the app artifact. For the type, specify "task". Here are a few examples:

```
dataflow:>app register --name task1 --type task --uri maven://com.example:mytask:1.0.2

dataflow:>app register --name task2 --type task --uri file:///Users/example/mytask-1.0.2.jar

dataflow:>app register --name task3 --type task --uri http://example.com/mytask-1.0.2.jar
```

When providing a URI with the `maven` scheme, the format should conform to the following:

```
maven://<groupId>:<artifactId>[:<extension>[:<classifier>]]:<version>
```

If you would like to register multiple apps at one time, you can store them in a properties file where the keys are formatted as `<type>.<name>` and the values are the URIs. For example, this would be a valid properties file:

```
task.foo=file:///tmp/foo.jar
task.bar=file:///tmp/bar.jar
```

Then use the `app import` command and provide the location of the properties file via `--uri`:

```
app import --uri file:///tmp/task-apps.properties
```

For convenience, we have the static files with application-URIs (for both maven and docker) available for all the out-of-the-box Task app-starters. You can point to this file and import all the application-URIs in bulk. Otherwise, as explained in previous paragraphs, you can register them individually or have your own custom property file with only the required application-URIs in it. It is recommended, however, to have a "focused" list of desired application-URIs in a custom property file.

List of available static property files:

Artifact Type	Stable Release	SNAPSHOT Release
Maven	http://bit.ly/Belmont-GA-task-applications-maven	http://bit.ly/Belmont-BUILD-SNAPSHOT-task-applications-maven
Docker	http://bit.ly/Belmont-GA-task-applications-docker	http://bit.ly/Belmont-BUILD-SNAPSHOT-task-applications-docker

For example, if you would like to register all out-of-the-box task applications in bulk, you can with the following command.

```
dataflow:>app import --uri http://bit.ly/Belmont-GA-task-applications-maven
```

You can also pass the `--local` option (which is `TRUE` by default) to indicate whether the properties file location should be resolved within the shell process itself. If the location should be resolved from the Data Flow Server process, specify `--local false`.

When using either `app register` or `app import`, if a task app is already registered with the provided name, it will not be overridden by default. If you would like to override the pre-existing task app, then include the `--force` option.

Note

In some cases the Resource is resolved on the server side, whereas in others the URI will be passed to a runtime container instance where it is resolved. Consult the specific documentation of each Data Flow Server for more detail.

37.3 Creating a Task

Create a Task Definition from a Task App by providing a definition name as well as properties that apply to the task execution. Creating a task definition can be done via the restful API or the shell. To

create a task definition using the shell, use the `task create` command to create the task definition. For example:

```
dataflow:>task create mytask --definition "timestamp --format=\"%yyyy\""
Created new task 'mytask'
```

A listing of the current task definitions can be obtained via the restful API or the shell. To get the task definition list using the shell, use the `task list` command.

37.4 Launching a Task

An adhoc task can be launched via the restful API or via the shell. To launch an ad-hoc task via the shell use the `task launch` command. For example:

```
dataflow:>task launch mytask
Launched task 'mytask'
```

When a task is launched, any properties that need to be passed as the command line arguments to the task application can be set when launching the task as follows:

```
dataflow:>task launch mytask --arguments "--server.port=8080,--foo=bar"
```

Additional properties meant for a `TaskLauncher` itself can be passed in using a `--properties` option. Format of this option is a comma delimited string of properties prefixed with `app.<task definition name>.<property>`. Properties are passed to `TaskLauncher` as application properties and it is up to an implementation to choose how those are passed into an actual task application. If the property is prefixed with `deployer` instead of `app` it is passed to `TaskLauncher` as a deployment property and its meaning may be `TaskLauncher` implementation specific.

```
dataflow:>task launch mytask --properties "deployer.timestamp.foo1=bar1,app.timestamp.foo2=bar2"
```

Common application properties

In addition to configuration via DSL, Spring Cloud Data Flow provides a mechanism for setting common properties to all the task applications that are launched by it. This can be done by adding properties prefixed with `spring.cloud.dataflow.applicationProperties.task` when starting the server. When doing so, the server will pass all the properties, without the prefix, to the instances it launches.

For example, all the launched applications can be configured to use the properties `foo` and `fizz` by launching the Data Flow server with the following options:

```
--spring.cloud.dataflow.applicationProperties.task.foo=bar
--spring.cloud.dataflow.applicationProperties.task.fizz=bar2
```

This will cause the properties `foo=bar` and `fizz=bar2` to be passed to all the launched applications.

Note

Properties configured using this mechanism have lower precedence than task deployment properties. They will be overridden if a property with the same key is specified at task launch time (e.g. `app.trigger.fizz` will override the common property).

37.5 Reviewing Task Executions

Once the task is launched the state of the task is stored in a relational DB. The state includes:

- Task Name
- Start Time
- End Time
- Exit Code
- Exit Message
- Last Updated Time
- Parameters

A user can check the status of their task executions via the restful API or by the shell. To display the latest task executions via the shell use the `task execution list` command.

To get a list of task executions for just one task definition, add `--name` and the task definition name, for example `task execution list --name foo`. To retrieve full details for a task execution use the `task display` command with the id of the task execution, for example `task display --id 549`.

37.6 Destroying a Task

Destroying a Task Definition will remove the definition from the definition repository. This can be done via the restful API or via the shell. To destroy a task via the shell use the `task destroy` command. For example:

```
dataflow:>task destroy mytask
Destroyed task 'mytask'
```

The task execution information for previously launched tasks for the definition will remain in the task repository.

Note

This will not stop any currently executing tasks for this definition, instead it just removes the task definition from the database.

38. Task Repository

Out of the box Spring Cloud Data Flow offers an embedded instance of the H2 database. The H2 is good for development purposes but is not recommended for production use.

38.1 Configuring the Task Execution Repository

To add a driver for the database that will store the Task Execution information, a dependency for the driver will need to be added to a maven pom file and the Spring Cloud Data Flow will need to be rebuilt. Since Spring Cloud Data Flow is comprised of an SPI for each environment it supports, please review the SPI's documentation on which POM should be updated to add the dependency and how to build. This document will cover how to setup the dependency for local SPI.

Local

1. Open the `spring-cloud-dataflow-server-local/pom.xml` in your IDE.
2. In the `dependencies` section add the dependency for the database driver required. In the sample below `postgresql` has been chosen.

```
<dependencies>
...
  <dependency>
    <groupId>org.postgresql</groupId>
    <artifactId>postgresql</artifactId>
  </dependency>
...
</dependencies>
```

3. Save the changed `pom.xml`
4. Build the application as described here: [Building Spring Cloud Data Flow](#)

Task Application Repository

When launching a task application be sure that the database driver that is being used by Spring Cloud Data Flow is also a dependency on the task application. For example if your Spring Cloud Data Flow is set to use `Postgresql`, be sure that the task application *also* has `Postgresql` as a dependency.

Note

When executing tasks externally (i.e. command line) and you wish for Spring Cloud Data Flow to show the TaskExecutions in its UI, be sure that common datasource settings are shared among the both. By default Spring Cloud Task will use a local H2 instance and the execution will not be recorded to the database used by Spring Cloud Data Flow.

38.2 Datasource

To configure the datasource Add the following properties to the `dataflow-server.yml` or via environment variables:

- a. `spring.datasource.url`
- b. `spring.datasource.username`

c. `spring.datasource.password`

d. `spring.datasource.driver-class-name`

For example adding postgres would look something like this:

- Environment variables:

```
export spring_datasource_url=jdbc:postgresql://localhost:5432/mydb
export spring_datasource_username=myuser
export spring_datasource_password=mypass
export spring_datasource_driver-class-name="org.postgresql.Driver"
```

- `dataflow-server.yml`

```
spring:
  datasource:
    url: jdbc:postgresql://localhost:5432/mydb
    username: myuser
    password: mypass
    driver-class-name:org.postgresql.Driver
```

39. Subscribing to Task/Batch Events

You can also tap into various task/batch events when the task is launched. If the task is enabled to generate task and/or batch events (with the additional dependencies `spring-cloud-task-stream` and `spring-cloud-stream-binder-kafka`, in the case of Kafka as the binder), those events are published during the task lifecycle. By default, the destination names for those published events on the broker (rabbit, kafka etc.,) are the event names themselves (for instance: `task-events`, `job-execution-events` etc.,).

```
dataflow:>task create myTask --definition "myBatchJob"
dataflow:>task launch myTask
dataflow:>stream create task-event-subscriber1 --definition ":task-events > log" --deploy
```

You can control the destination name for those events by specifying explicit names when launching the task such as:

```
dataflow:>task launch myTask --properties "spring.cloud.stream.bindings.task-
events.destination=myTaskEvents"
dataflow:>stream create task-event-subscriber2 --definition ":myTaskEvents > log" --deploy
```

The default Task/Batch event and destination names on the broker are enumerated below:

Table 39.1. Task/Batch Event Destinations

Event	Destination
Task events	task-events
Job Execution events	job-execution-events
Step Execution events	step-execution-events
Item Read events	item-read-events
Item Process events	item-process-events
Item Write events	item-write-events
Skip events	skip-events

40. Launching Tasks from a Stream

You can launch a task from a stream by using one of the available `task-launcher` sinks. Currently the platforms supported via the `task-launcher` sinks are [local](#), [Cloud Foundry](#), and [Yarn](#).

Note

`task-launcher-local` is meant for development purposes only.

A `task-launcher` sink expects a message containing a [TaskLaunchRequest](#) object in its payload. From the `TaskLaunchRequest` object the `task-launcher` will obtain the URI of the artifact to be launched as well as the environment properties, command line arguments, deployment properties and application name to be used by the task.

The [task-launcher-local](#) can be added to the available sinks by executing the app register command as follows (for the Rabbit Binder):

```
app register --name task-launcher-local --type sink --uri maven://
org.springframework.cloud.stream.app:task-launcher-local-sink-rabbit:jar:1.2.0.RELEASE
```

In the case of a maven based task that is to be launched, the `task-launcher` application is responsible for downloading the artifact. You **must** configure the `task-launcher` with the appropriate configuration of [Maven Properties](#) such as `--maven.remote-repositories.repo1.url=http://repo.spring.io/libs-milestone"` to resolve artifacts, in this case against a milestone repo. Note that this repo can be different than the one used to register the `task-launcher` application itself.

40.1 TriggerTask

One way to launch a task using the `task-launcher` is to use the [triggertask](#) source. The `triggertask` source will emit a message with a `TaskLaunchRequest` object containing the required launch information. The `triggertask` can be added to the available sources by executing the app register command as follows (for the Rabbit Binder):

```
app register --type source --name triggertask --uri maven://
org.springframework.cloud.stream.app:triggertask-source-rabbit:1.2.0.RELEASE
```

An example of this would be to launch the timestamp task once every 60 seconds, the stream to implement this would look like:

```
stream create foo --definition "triggertask --triggertask.uri=maven://
org.springframework.cloud.task.app:timestamp-task:jar:1.2.0.RELEASE --trigger.fixed-
delay=60 --triggertask.environment-properties=spring.datasource.url=jdbc:h2:tcp://
localhost:19092/mem:dataflow,spring.datasource.username=sa | task-launcher-local --maven.remote-
repositories.repo1.url=http://repo.spring.io/libs-release" --deploy
```

If you execute `runtime apps` you can find the log file for the task launcher sink. Tailing that file you can find the log file for the launched tasks. The setting of `triggertask.environment-properties` is so that all the task executions can be collected in the same H2 database used in the local version of the Data Flow Server. You can then see the list of task executions using the shell command `task execution list`

```
dataflow:>task execution list
#####
# Task Name      #ID#      Start Time      #      End Time      #Exit Code#
#####
```

```
#timestamp-task_26176#4 #Tue May 02 12:13:49 EDT 2017#Tue May 02 12:13:49 EDT 2017#0 #
#timestamp-task_32996#3 #Tue May 02 12:12:49 EDT 2017#Tue May 02 12:12:49 EDT 2017#0 #
#timestamp-task_58971#2 #Tue May 02 12:11:50 EDT 2017#Tue May 02 12:11:50 EDT 2017#0 #
#timestamp-task_13467#1 #Tue May 02 12:10:50 EDT 2017#Tue May 02 12:10:50 EDT 2017#0 #
#####
```

40.2 TaskLaunchRequest-transform

Another option to start a task using the `task-launcher` would be to create a stream using the [Tasklaunchrequest-transform](#) processor to translate a message payload to a `TaskLaunchRequest`.

The `tasklaunchrequest-transform` can be added to the available processors by executing the `app register` command as follows (for the Rabbit Binder):

```
app register --type processor --name tasklaunchrequest-transform --uri maven://
org.springframework.cloud.stream.app:tasklaunchrequest-transform-processor-rabbit:1.2.0.RELEASE
```

For example:

```
stream create task-stream --definition "http --port=9000 | tasklaunchrequest-transform --uri=maven://
org.springframework.cloud.task.app:timestamp-task:jar:1.2.0.RELEASE | task-launcher-local --
maven.remote-repositories.repo1.url=http://repo.spring.io/libs-release"
```

41. Composed Tasks

Spring Cloud Data Flow allows a user to create a directed graph where each node of the graph is a task application. This is done by using the DSL for composed tasks. A composed task can be created via the RESTful API, the Spring Cloud Data Flow Shell, or the Spring Cloud Data Flow UI.

41.1 Configuring the Composed Task Runner in Spring Cloud Data Flow

Composed tasks are executed via a task application called the [Composed Task Runner](#).

Registering the Composed Task Runner application

Out of the box the Composed Task Runner application is not registered with Spring Cloud Data Flow. So, to launch composed tasks we must first register the Composed Task Runner as an application with Spring Cloud Data Flow as follows:

```
app register --name composed-task-runner --type task --uri maven://
org.springframework.cloud.task.app:composedtaskrunner-task:<DESIRED_VERSION>
```

You can also configure Spring Cloud Data Flow to use a different task definition name for the composed task runner. This can be done by setting the `spring.cloud.dataflow.task.composedTaskRunnerName` property to the name of your choice. You can then register the composed task runner application with the name you set using that property.

Configuring the Composed Task Runner application

The Composed Task Runner application has a `dataflow.server.uri` property that is used for validation and for launching child tasks. This defaults to `localhost:9393`. If you run a distributed Spring Cloud Data Flow server, like you would do if you deploy the server on Cloud Foundry, YARN or Kubernetes, then you need to provide the URI that can be used to access the server. You can either provide this `dataflow.server.uri` property for the Composed Task Runner application when launching a composed task, or you can provide a `spring.cloud.dataflow.server.uri` property for the Spring Cloud Data Flow server when it is started. For the latter case the `dataflow.server.uri` Composed Task Runner application property will be automatically set when a composed task is launched.

41.2 Creating, Launching, and Destroying a Composed Task

Creating a Composed Task

The DSL for the composed tasks is used when creating a task definition via the task create command. For example:

```
dataflow:> app register --name timestamp --type task --uri maven://
org.springframework.cloud.task.app:timestamp-task:<DESIRED_VERSION>
dataflow:> app register --name mytaskapp --type task --uri file:///home/tasks/mytask.jar
dataflow:> task create my-composed-task --definition "mytaskapp && timestamp"
dataflow:> task launch my-composed-task
```

In the example above we assume that the applications to be used by our composed task have not been registered yet. So the first two steps we register two task applications. We then create our composed task definition by using the task create command. The composed task DSL in the example above will, when launched, execute mytaskapp and then execute the timestamp application.

But before we launch the my-composed-task definition, we can view what Spring Cloud Data Flow generated for us. This can be done by executing the task list command.

```
dataflow:>task list
#####
#      Task Name      #      Task Definition
#####
#my-composed-task      #mytaskapp && timestamp
#my-composed-task-mytaskapp#mytaskapp
#my-composed-task-timestamp#timestamp
```

Spring Cloud Data Flow created three task definitions, one for each of the applications that comprises our composed task (my-composed-task-mytaskapp and my-composed-task-timestamp) as well as the composed task (my-composed-task) definition. We also see that each of the generated names for the child tasks is comprised of the name of the composed task and the name of the application separated by a dash -. i.e. *my-composed-task - mytaskapp*.

Task Application Parameters

The task applications that comprise the composed task definition can also contain parameters. For example:

```
dataflow:> task create my-composed-task --definition "mytaskapp --displayMessage=hello && timestamp --format=YYYY"
```

Launching a Composed Task

Launching a composed task is done the same way as launching a stand-alone task. i.e.

```
task launch my-composed-task
```

Once the task is launched and assuming all the tasks complete successfully you will see three task executions when executing a task execution list. For example:

```
dataflow:>task execution list
#####
#      Task Name      #ID #      Start Time      #      End Time      #Exit Code#
#####
#my-composed-task-timestamp#713#Wed Apr 12 16:43:07 EDT 2017#Wed Apr 12 16:43:07 EDT 2017#0      #
#my-composed-task-mytaskapp#712#Wed Apr 12 16:42:57 EDT 2017#Wed Apr 12 16:42:57 EDT 2017#0      #
#my-composed-task      #711#Wed Apr 12 16:42:55 EDT 2017#Wed Apr 12 16:43:15 EDT 2017#0      #
#####
```

In the example above we see that my-compose-task launched and it also launched the other tasks in sequential order and all of them executed successfully with "Exit Code" as 0.

Exit Statuses

The following list shows how the Exit Status will be set for each step (task) contained in the composed task following each step execution.

- If the TaskExecution has an ExitMessage that will be used as the ExitStatus
- If no ExitMessage is present and the ExitCode is set to zero then the ExitStatus for the step will be COMPLETED.
- If no ExitMessage is present and the ExitCode is set to any non zero number then the ExitStatus for the step will be FAILED.

Destroying a Composed Task

The same command used to destroy a stand-alone task is the same as destroying a composed task. The only difference is that destroying a composed task will also destroy the child tasks associated with it. For example

```
dataflow:>task list
#####
#      Task Name      #      Task Definition
#####
#my-composed-task      #mytaskapp && timestamp
#my-composed-task-mytaskapp#mytaskapp
#my-composed-task-timestamp#timestamp
...
dataflow:>task destroy my-composed-task
dataflow:>task list
#####
#      Task Name      #      Task Definition
#####
#####
```

Stopping a Composed Task

In cases where a composed task execution needs to be stopped. This can be done via the:

- RESTful API
- Spring Cloud Data Flow Dashboard by selecting the Job's tab and then clicking the stop button by the job execution that needs to be stopped.

The composed task run will be stopped when the currently running child task completes. The step associated with the child task that was running at the time that the composed task was stopped will be marked as `STOPPED` as well as the composed task job execution.

Restarting a Composed Task

In cases where a composed task fails during execution and the status of the composed task is `FAILED` then the task can be restarted. This can be done via the:

- RESTful API
- Shell by launching the task using the same parameters
- Spring Cloud Data Flow Dashboard by selecting the Job's tab and then clicking the restart button by the job execution that needs to be restarted.

Note

Restarting a Composed Task job that has been stopped (via the Spring Cloud Data Flow Dashboard or RESTful API), will relaunch the `STOPPED` child task, and then launch the remaining (unlaunched) child tasks in the specified order.

41.3 Composed Task DSL

Conditional Execution

Conditional execution is expressed using a double ampersand symbol `&&`. This allows each task in the sequence to be launched only if the previous task successfully completed. For example:

```
task create my-composed-task --definition "foo && bar"
```

When the composed task `my-composed-task` is launched, it will launch the task `foo` and if it completes successfully, then the task `bar` will be launched. If the `foo` task fails, then the task `bar` will not launch.

You can also use the Spring Cloud Data Flow Dashboard to create your conditional execution. By using the designer to drag and drop applications that are required, and connecting them together to create your directed graph. For example:

Figure 41.1. Conditional Execution

The diagram above is a screen capture of the directed graph as it being created using the Spring Cloud Data Flow Dashboard. We see that are 4 components in the diagram that comprise a conditional execution:

- Start icon - All directed graphs start from this symbol. There will only be one.
- Task icon - Represents each task in the directed graph.
- End icon - Represents the termination of a directed graph.
- Solid line arrow - Represents the flow conditional execution flow between:
 - Two applications
 - The start control node and an application
 - An application and the end control node

**Note**

You can view a diagram of your directed graph by clicking the detail button next to the composed task definition on the definitions tab.

Transitional Execution

The DSL supports fine grained control over the transitions taken during the execution of the directed graph. Transitions are specified by providing a condition for equality based on the exit status of the previous task. A task transition is represented by the following symbol `->`.

Basic Transition

A basic transition would look like the following:

```
task create my-transition-composed-task --definition "foo 'FAILED' -> bar 'COMPLETED' -> baz"
```

In the example above `foo` would launch and if it had an exit status of `FAILED`, then the `bar` task would launch. If the exit status of `foo` was `COMPLETED` then `baz` would launch. All other statuses returned by `foo` will have no effect and task would terminate normally.

Using the Spring Cloud Data Flow Dashboard to create the same "basic transition" would look like:

Figure 41.2. Basic Transition

The diagram above is a screen capture of the directed graph as it being created using the Spring Cloud Data Flow Dashboard. Notice that there are 2 different types of connectors:

- Dashed line - Is the line used to represent transitions from the application to one of the possible destination applications.
- Solid line - Used to connect applications in a conditional execution or a connection between the application and a control node (end, start).

When creating a transition, link the application to each of possible destination using the connector. Once complete go to each connection and select it by clicking it. A bolt icon should appear, click that icon and enter the exit status required for that connector. The solid line for that connector will turn to a dashed line.

Transition With a Wildcard

Wildcards are supported for transitions by the DSL for example:

```
task create my-transition-composed-task --definition "foo 'FAILED' -> bar '*' -> baz"
```

In the example above `foo` would launch and if it had an exit status of `FAILED`, then the `bar` task would launch. Any exit status of `foo` other than `FAILED` then `baz` would launch.

Using the Spring Cloud Data Flow Dashboard to create the same "transition with wildcard" would look like:

Figure 41.3. Basic Transition With Wildcard

Transition With a Following Conditional Execution

A transition can be followed by a conditional execution so long as the wildcard is not used. For example:

```
task create my-transition-conditional-execution-task --definition "foo 'FAILED' -> bar 'UNKNOWN' -> baz
&& qux && quux"
```

In the example above `foo` would launch and if it had an exit status of `FAILED`, then the `bar` task would launch. If `foo` had an exit status of `UNKNOWN` then `baz` would launch. Any exit status of `foo` other than `FAILED` or `UNKNOWN` then `qux` would launch and upon successful completion `quux` would launch.

Using the Spring Cloud Data Flow Dashboard to create the same "transition with conditional execution" would look like:

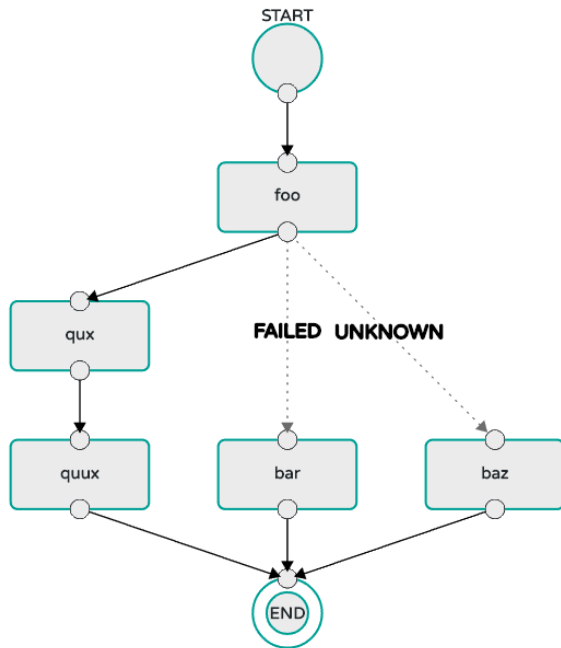

Figure 41.4. Transition With Conditional Execution

Note

In this diagram we see the dashed line (transition) connecting the `foo` application to the target applications, but a solid line connecting the conditional executions between `foo`, `quux`, and `quux`.

Split Execution

Splits allow for multiple tasks within a composed task to be run in parallel. It is denoted by using angle brackets `<>` to group tasks and flows that are to be run in parallel. These tasks and flows are separated by the double pipe `||`. For example:

```
task create my-split-task --definition "<foo || bar || baz>"
```

The example above will launch tasks `foo`, `bar` and `baz` in parallel.

Using the Spring Cloud Data Flow Dashboard to create the same "split execution" would look like:

Figure 41.5. Split

With the task DSL a user may also execute multiple split groups in succession. For example:

```
task create my-split-task --definition "<foo || bar || baz> && <quux || quux>"
```

In the example above tasks `foo`, `bar` and `baz` will be launched in parallel, once they all complete then tasks `quux`, `quux` will be launched in parallel. Once they complete the composed task will end. However if `foo`, `bar`, or `baz` fails then, the split containing `quux` and `quux` will not launch.

Using the Spring Cloud Data Flow Dashboard to create the same "split with multiple groups" would look like:

Figure 41.6. Split as a part of a conditional execution

Notice that there is a `SYNC` control node that is by the designer when connecting two consecutive splits.

Split Containing Conditional Execution

A split can also have a conditional execution within the angle brackets. For example:

```
task create my-split-task --definition "<foo && bar || baz>"
```

In the example above we see that `foo` and `baz` will be launched in parallel, however `bar` will not launch until `foo` completes successfully.

Using the Spring Cloud Data Flow Dashboard to create the same "split containing conditional execution" would look like:

Figure 41.7. Split with conditional execution

Part VII. Dashboard

This section describe how to use the Dashboard of Spring Cloud Data Flow.

42. Introduction

Spring Cloud Data Flow provides a browser-based GUI and it currently includes 6 tabs:

- **Apps** Lists all available applications and provides the control to register/unregister them
- **Runtime** Provides the Data Flow cluster view with the list of all running applications
- **Streams** List, create, deploy, and destroy Stream Definitions
- **Tasks** List, create, launch and destroy Task Definitions
- **Jobs** Perform Batch Job related functions
- **Analytics** Create data visualizations for the various analytics applications

Upon starting Spring Cloud Data Flow, the Dashboard is available at:

`http://<host>:<port>/dashboard`

For example: <http://localhost:9393/dashboard>

If you have enabled https, then it will be located at `https://localhost:9393/dashboard`. If you have enabled security, a login form is available at `http://localhost:9393/dashboard/#/login`.

Note

The default Dashboard server port is 9393

About

Spring Cloud Data Flow is a unified, distributed, and extensible system for data ingestion, real time analytics, batch processing, and data export. The project's goal is to simplify the development of big data applications.

Dataflow Server Implementation	
Name	spring-cloud-dataflow-server-local
Version	1.0.0.BUILD-SNAPSHOT (7188a69)
Description	Local Data Flow Server

Figure 42.1. The Spring Cloud Data Flow Dashboard

43. Apps

The *Apps* section of the Dashboard lists all the available applications and provides the control to register/unregister them (if applicable). It is possible to import a number of applications at once using the **Bulk Import Applications** action.

The screenshot shows the 'Apps' section of the Spring Cloud Data Flow Dashboard. At the top, there's a navigation bar with tabs: APPS (selected), RUNTIME, STREAMS, TASKS, JOBS, ANALYTICS, and ABOUT. Below the navigation bar, the 'Apps' section is titled, and a subtitle states: 'This section lists all the available applications and provides the control to register/unregister them (if applicable).' Below this, there's a section titled 'All Applications' with three buttons: '+ Register Application(s)', 'Unregister Application(s)', and 'Bulk Import Applications' (highlighted). To the right of these buttons is a 'Quick filter' input field. Below the buttons is a table listing applications:

Name	Type	URI	Actions
file	source	maven://org.springframework.cloud.stream.app:file-source-rabbit:1.0.2.RELEASE	[Search] [Delete]
ftp	source	maven://org.springframework.cloud.stream.app:ftp-source-rabbit:1.0.2.RELEASE	[Search] [Delete]
gemfire	source	maven://org.springframework.cloud.stream.app:gemfire-source-rabbit:1.0.2.RELEASE	[Search] [Delete]
gemfire-cq	source	maven://org.springframework.cloud.stream.app:gemfire-cq-source-rabbit:1.0.2.RELEASE	[Search] [Delete]
http	source	maven://org.springframework.cloud.stream.app:http-source-rabbit:1.0.2.RELEASE	[Search] [Delete]
jdbc	source	maven://org.springframework.cloud.stream.app:jdbc-source-rabbit:1.0.2.RELEASE	[Search] [Delete]
jms	source	maven://org.springframework.cloud.stream.app:jms-source-rabbit:1.0.2.RELEASE	[Search] [Delete]

Figure 43.1. List of Available Applications

43.1 Bulk Import of Applications

The bulk import applications page provides numerous options for defining and importing a set of applications in one go. For bulk import the application definitions are expected to be expressed in a properties style:

```
<type>.<name> = <coordinates>
```

For example:

```
task.timestamp=maven://org.springframework.cloud.task.app:timestamp-
task:1.2.0.RELEASE
```

```
processor.transform=maven://org.springframework.cloud.stream.app:transform-
processor-rabbit:1.2.0.RELEASE
```

At the top of the bulk import page an *Uri* can be specified that points to a properties file stored elsewhere, it should contain properties formatted as above. Alternatively, using the textbox labeled *Apps as Properties* it is possible to directly list each property string. Finally, if the properties are stored in a local file the *Select Properties File* option will open a local file browser to select the file. After setting your definitions via one of these routes, click **Import**.

At the bottom of the page there are quick links to the property files for common groups of stream apps and task apps. If those meet your needs, simply select your appropriate variant (rabbit, kafka, docker, etc) and click the **Import** action on those lines to immediately import all those applications.

The screenshot shows the 'Bulk Import Applications' page in the Spring Cloud Data Flow console. The page has a dark header with the Spring logo and navigation links: APPS, RUNTIME, STREAMS, TASKS, JOBS, ANALYTICS, and ABOUT. The 'APPS' link is highlighted in teal. Below the header, the page title 'Bulk Import Applications' is followed by a brief instruction: 'Import and register applications in bulk. Simply provide a URI that points to the location of the properties file where the keys are formatted as type.name and the values are the URIs of the apps. For convenience, a list of out-of-the-box Stream and Task app starters is provided below, as well.'

The main form area contains three sections:

- Uri:** A text input field with the placeholder '<http://url.to.properties>'. Below it, a note says 'Please provide a valid URI pointing to the respective properties file.'
- OR:** A section separator.
- Apps as Properties:** A text area with an example of properties: 'task.timestamp=maven://o.s.cloud.task.app:timestamp-task:1.2.3.RELEASE' and 'task.spark-client=maven://o.s.cloud.task.app:spark-client-task:1.2.3.RELEASE'. Below the text area, a note says 'Please provide a valid properties where the keys are formatted as type.name and the values are the URIs of the apps.'

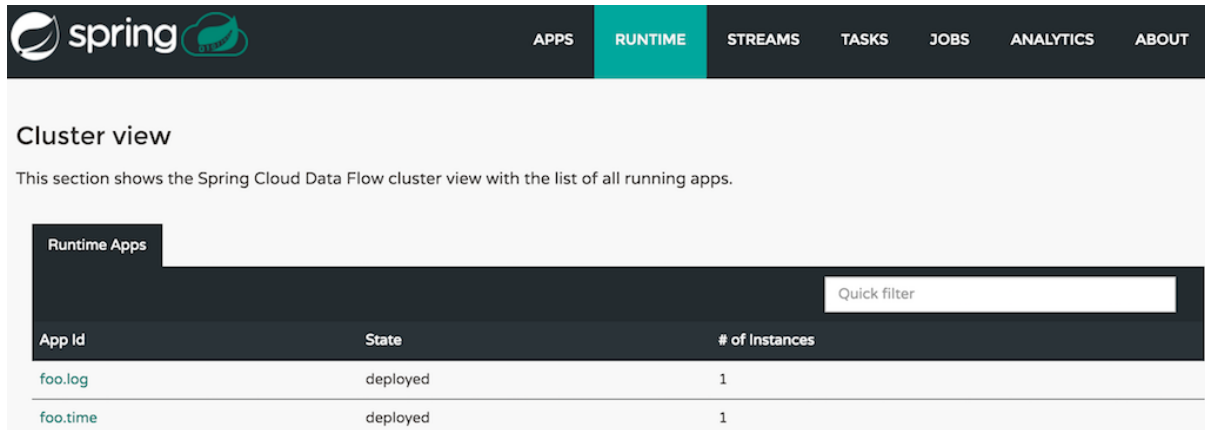

At the bottom of the form, there is a 'Select Properties File' section with a 'Choose File' button and the text 'No file chosen'. Below this, a note says 'Please provide a text file containing properties. This will be used to populate the text area above.' There is also a checkbox labeled 'Force' with a question mark icon.

At the bottom right of the form, there are two buttons: 'Cancel' and 'Import'.

Figure 43.2. Bulk Import Applications

44. Runtime

The *Runtime* section of the Dashboard application shows the Spring Cloud Data Flow cluster view with the list of all running applications. For each runtime app the state of the deployment and the number of deployed instances is shown. A list of the used deployment properties is available by clicking on the app id.

The screenshot shows the 'Runtime' tab selected in the dashboard. Below the navigation bar, the 'Cluster view' section contains a description and a table of runtime apps. The table has columns for App Id, State, and # of Instances. Two apps are listed: 'foo.log' and 'foo.time', both in a 'deployed' state with 1 instance each. A 'Quick filter' input field is located to the right of the table header.

App Id	State	# of Instances
foo.log	deployed	1
foo.time	deployed	1

Figure 44.1. List of Running Applications

45. Streams

The *Streams* section of the Dashboard provides the *Definitions* tab that provides a listing of Stream definitions. There you have the option to **deploy** or **undeploy** those stream definitions. Additionally you can remove the definition by clicking on **destroy**. Each row includes an arrow on the left, which can be clicked to see a visual representation of the definition. Hovering over the boxes in the visual representation will show more details about the apps including any options passed to them. In this screenshot the timer stream has been expanded to show the visual representation:

The screenshot shows the 'Definitions' tab in the Spring Cloud Data Flow Dashboard. At the top, there are buttons for 'Expand All' and 'Collapse All', and a 'Quick filter' input field. Below this is a table with columns: Name, Definition, Status, and Actions. The table lists three streams: 'minutes', 'seconds', and 'timer'. The 'timer' stream is expanded, showing a visual representation of its definition. The visual representation shows a 'time' component connected to a 'log' component. The 'timer' stream is currently expanded, showing a visual representation of its definition. The visual representation shows a 'time' component connected to a 'log' component. The 'timer' stream is currently expanded, showing a visual representation of its definition. The visual representation shows a 'time' component connected to a 'log' component.

Name	Definition	Status	Actions
minutes	:timer.time > transform --expression=payload.substring(2,4) log	deployed	Details Undeploy Deploy Destroy
seconds	:timer.time > transform --expression=payload.substring(4) log	deployed	Details Undeploy Deploy Destroy
timer	time --date-format=hhmmss log	deployed	Details Undeploy Deploy Destroy

The visual representation of the 'timer' stream shows a 'time' component connected to a 'log' component. The 'time' component is a box with a right-pointing arrow and the text 'time'. The 'log' component is a box with a right-pointing arrow and the text 'log'. A line connects the output of the 'time' component to the input of the 'log' component.

Figure 45.1. List of Stream Definitions

If the **details** button is clicked the view will change to show a visual representation of that stream and also any related streams. In the above example, if clicking **details** for the timer stream, the view will change to the one shown below which clearly shows the relationship between the three streams (two of them are tapping into the timer stream).

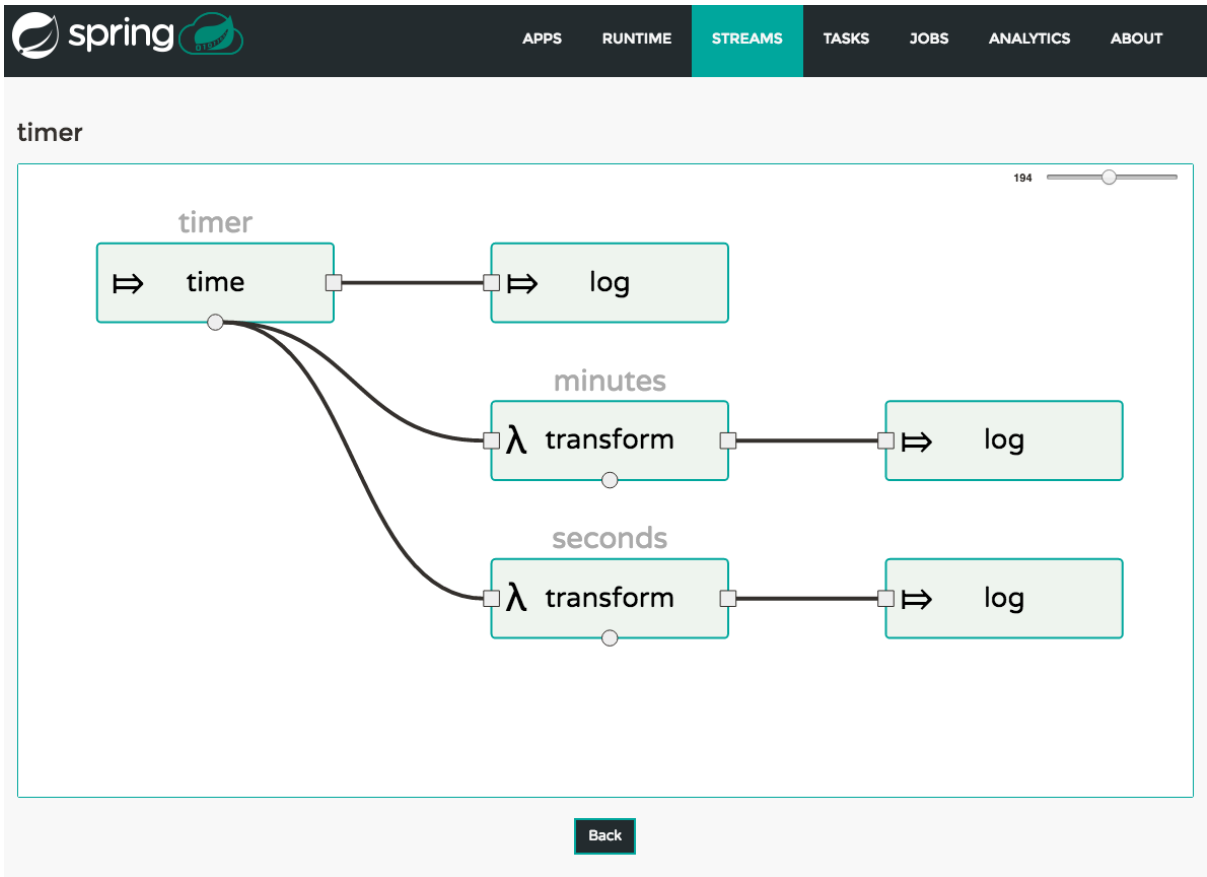

Figure 45.2. Stream Details Page

46. Create Stream

The *Create Stream* section of the Dashboard includes the [Spring Flo](#) designer tab that provides the canvas application, offering an interactive graphical interface for creating data pipelines.

In this tab, you can:

- Create, manage, and visualize stream pipelines using DSL, a graphical canvas, or both
- Write pipelines via DSL with content-assist and auto-complete
- Use auto-adjustment and grid-layout capabilities in the GUI for simpler and interactive organization of pipelines

Watch this [screencast](#) that highlights some of the "Flo for Spring Cloud Data Flow" capabilities. Spring Flo [wiki](#) includes more detailed content on core Flo capabilities.

The screenshot displays the Spring Cloud Data Flow Dashboard's 'Streams' section. At the top, a navigation bar includes 'APPS', 'RUNTIME', 'STREAMS' (highlighted), 'TASKS', 'JOBS', 'ANALYTICS', and 'ABOUT'. Below the navigation bar, the 'Streams' section header is followed by the instruction 'Create a stream using text based input or the visual editor.' The 'Create Stream' tab is active, showing a DSL editor with the following code:

```
1 STREAM_1=time | scriptable-transform --script="return '#{payload.tr('^A-Za-z0-9', '')}'" --language=ruby | log
2 :STREAM_1.time > scriptable-transform --script="function double(p) {\n    return p + '--' + p;\n}\ndouble(payload);" --
  language=javascript | log
3 :STREAM_1.time > scriptable-transform --script="return payload + ':' + payload" --language=groovy | log
```

Below the DSL editor, a 'source' sidebar lists various connectors: file, ftp, http, jdbc, jms, and load-gener... The main visual canvas, titled 'STREAM_1', shows a 'time' source connector connected to three parallel 'scriptable-transform' tasks. Each task is followed by a 'log' sink connector, representing a branching pipeline structure.

Figure 46.1. Flo for Spring Cloud Data Flow

47. Tasks

The *Tasks* section of the Dashboard currently has three tabs:

- Apps
- Definitions
- Executions

47.1 Apps

Apps encapsulate a unit of work into a reusable component. Within the Data Flow runtime environment *Apps* allow users to create definitions for *Streams* as well as *Tasks*. Consequently, the *Apps* tab within the *Tasks* section allows users to create *Task* definitions.

Note

You will also use this tab to create Batch Jobs.

spring 			APPS	RUNTIME	STREAMS	TASKS	JOBS	ANALYTICS	ABOUT
Tasks									
This section lists all available task apps. You have the ability to view app details and to create task definitions.									
<div>Apps</div> <div>Definitions</div> <div>Executions</div>									
Name	Coordinates							Actions	
spark-client									
spark-cluster									
spark-yarn									
sqoop-job									
sqoop-tool									
timestamp									

Figure 47.1. List of Task Apps

On this screen you can perform the following actions:

- View details such as the task app options.
- Create a Task Definition from the respective App.

Create a Task Definition from a selected Task App

On this screen you can create a new Task Definition. As a minimum you must provide a name for the new definition. You will also have the option to specify various properties that are used during the deployment of the app.

Note

Each parameter is only included if the *Include* checkbox is selected.

View Task App Details

On this page you can view the details of a selected task app, including the list of available options (properties) for that app.

47.2 Definitions

This page lists the Data Flow Task definitions and provides actions to **launch** or **destroy** those tasks. It also provides a shortcut operation to define one or more tasks using simple textual input, indicated by the **bulk define tasks** button.

Figure 47.2. List of Task Definitions

Creating Task Definitions using the bulk define interface

After pressing **bulk define tasks**, the following screen will be shown.

Figure 47.3. Bulk Define Tasks

It includes a textbox where one or more definitions can be entered and then various actions performed on those definitions. The required input text format for task definitions is very basic, each line should be of the form:

```
<task-definition-name> = <task-application> <options>
```

For example:

```
demo-timestamp = timestamp --format=hhmmss
```

After entering any data a validator will run asynchronously to verify both the syntax and that the application name entered is a valid application and it supports the options specified. If validation fails the editor will show the errors with more information via tooltips.

To make it easier to enter definitions into the text area, content assist is supported. Pressing **Ctrl+Space** will invoke content assist to suggest simple task names (based on the line on which it is invoked), task applications and task application options. Press **ESC** to close the content assist window without taking a selection.

If the validator should not verify the applications or the options (for example if specifying non-whitelisted options to the applications) then turn off that part of validation by toggling the checkbox off on the **Verify Apps** button - the validator will then only perform syntax checking. When correctly validated, the **create** button will be clickable and on pressing it the UI will proceed to create each task definition. If there are any errors during creation then after creation finishes the editor will show any lines of input, as it cannot be used in task definitions. These can then be fixed up and creation repeated. There is an **import file** button to open a file browser on the local file system if the definitions are in a file and it is easier to import than copy/paste.

Note

Bulk loading of composed task definitions is not currently supported.

Creating Composed Task Definitions

The dashboard includes the Create Composed Task tab that provides the canvas application, offering a interactive graphical interface for creating composed tasks.

In this tab, you can:

- Create and visualize composed tasks using DSL, a graphical canvas, or both
- Use auto-adjustment and grid-layout capabilities in the GUI for simpler and interactive organization of the composed task

Figure 47.4. Composed Task Designer

Launching Tasks

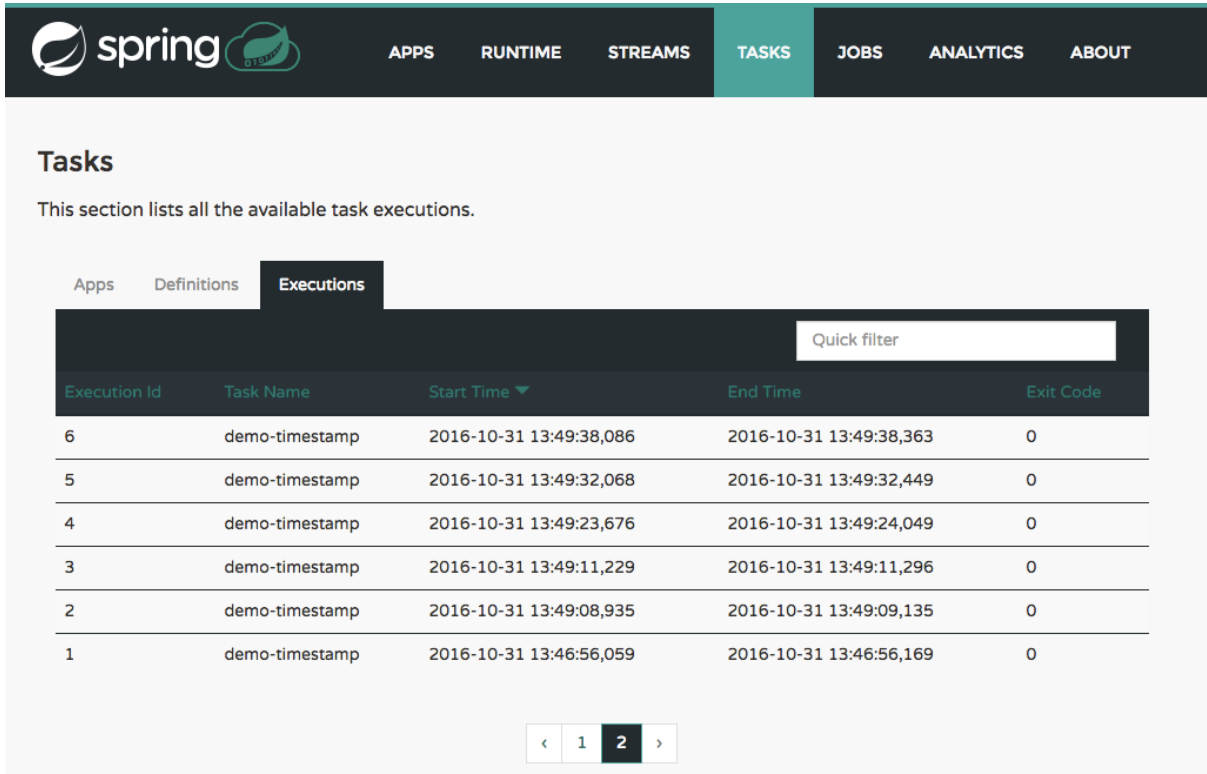

Once the task definition is created, they can be launched through the Dashboard as well. Navigate to the **Definitions** tab. Select the Task you want to launch by pressing **Launch**.

On the following screen, you can define one or more Task parameters by entering:

- Parameter Key
- Parameter Value

Task parameters are not typed.

47.3 Executions

The screenshot shows the Spring Cloud Data Flow console interface. The top navigation bar includes the Spring logo and tabs for APPS, RUNTIME, STREAMS, TASKS (selected), JOBS, ANALYTICS, and ABOUT. The main section is titled 'Tasks' and contains a sub-header 'This section lists all the available task executions.' Below this are tabs for Apps, Definitions, and Executions (selected). A 'Quick filter' input field is present. The main content is a table listing task executions with columns: Execution Id, Task Name, Start Time, End Time, and Exit Code. The table contains six rows of data for 'demo-timestamp' tasks. At the bottom, there is a pagination control showing page 2 of 2.

Execution Id	Task Name	Start Time	End Time	Exit Code
6	demo-timestamp	2016-10-31 13:49:38,086	2016-10-31 13:49:38,363	0
5	demo-timestamp	2016-10-31 13:49:32,068	2016-10-31 13:49:32,449	0
4	demo-timestamp	2016-10-31 13:49:23,676	2016-10-31 13:49:24,049	0
3	demo-timestamp	2016-10-31 13:49:11,229	2016-10-31 13:49:11,296	0
2	demo-timestamp	2016-10-31 13:49:08,935	2016-10-31 13:49:09,135	0
1	demo-timestamp	2016-10-31 13:46:56,059	2016-10-31 13:46:56,169	0

Figure 47.5. List of Task Executions

48. Jobs

The *Jobs* section of the Dashboard allows you to inspect **Batch Jobs**. The main section of the screen provides a list of Job Executions. **Batch Jobs** are **Tasks** that were executing one or more **Batch Job**. As such each Job Execution has a back reference to the **Task Execution Id** (Task Id).

In case of a failed job, you can also restart the task. When dealing with long-running Batch Jobs, you can also request to stop it.

Name	Task Id	Instance Id	Execution Id	Job Start Time	Step Executions Count	Status	Actions
job2	1	2	2	2016-06-13 13:57:58,294	1	COMPLETED	[Restart] [Stop] [Details]
job1	1	1	1	2016-06-13 13:57:58,241	1	COMPLETED	[Restart] [Stop] [Details]

Figure 48.1. List of Job Executions

48.1 List job executions

This page lists the Batch Job Executions and provides the option to **restart** or **stop** a specific job execution, provided the operation is available. Furthermore, you have the option to view the Job execution details.

The list of Job Executions also shows the state of the underlying Job Definition. Thus, if the underlying definition has been deleted, *deleted* will be shown.

Job execution details

Job Execution Details - Execution ID: 2 [Back](#)

Property	Value

Job Name	job2
Job Instance	2
Task Execution Id	1
Composed Job	✖
Job Parameters	
Start Time	2016-06-13 13:57:58,294
End Time	2016-06-13 13:57:58,317
Duration	23 ms
Status	COMPLETED
Exit Code	COMPLETED
Exit Message	N/A
Step Execution Count	1

Steps

Step Id	Step Name	Reads	Writes	Commits	Rollbacks	Duration	Status	Details
2	job2step1	0	0	1	0	8 ms	COMPLETED	Q

Figure 48.2. Job Execution Details

The Job Execution Details screen also contains a list of the executed steps. You can further drill into the *Step Execution Details* by clicking onto the magnifying glass.

Step execution details

On the top of the page, you will see progress indicator the respective step, with the option to refresh the indicator. Furthermore, a link is provided to view the *step execution history*.

The Step Execution details screen provides a complete list of all Step Execution Context key/value pairs.

Important

In case of exceptions, the *Exit Description* field will contain additional error information. Please be aware, though, that this field can only have a maximum of **2500 characters**. Therefore, in case of long exception stacktraces, trimming of error messages may occur. In that case, please refer to the server log files for further details.

Step Execution Progress

On this screen, you can see a progress bar indicator in regards to the execution of the current step. Under the **Step Execution History**, you can also view various metrics associated with the selected step such as **duration**, **read counts**, **write counts** etc.

Figure 48.3. Step Execution History

49. Analytics

The *Analytics* section of the Dashboard provided data visualization capabilities for the various analytics applications available in *Spring Cloud Data Flow*:

- Counters
- Field-Value Counters
- Aggregate Counters

For example, if you create a stream with a [Counter](#) application, you can now easily create the corresponding graph from within the **Dashboard** tab:

1. Under `Metric Type`, select `Counters` from the select box
2. Under `Stream`, select `tweetcount`
3. Under `Visualization`, select the desired chart option, `Bar Chart`

Using the icons to the right, you can add additional charts to the Dashboard, re-arrange the order of created dashboards or remove data visualizations.

Part VIII. ‘How-to’ guides

This section provides answers to some common ‘how do I do that...’ type of questions that often arise when using Spring Cloud Data Flow.

If you are having a specific problem that we don’t cover here, you might want to check out stackoverflow.com to see if someone has already provided an answer; this is also a great place to ask new questions (please use the `spring-cloud-dataflow` tag).

We’re also more than happy to extend this section; If you want to add a ‘how-to’ you can send us a [pull request](#).

50. Configure Maven Properties

You can set the maven properties such as local maven repository location, remote maven repositories and their authentication credentials including the proxy server properties via commandline properties when starting the Dataflow server or using the `SPRING_APPLICATION_JSON` environment property for the Dataflow server.

The remote maven repositories need to be configured explicitly if the apps are resolved using maven repository except for local Data Flow server. The other Data Flow server implementations (that use maven resources for app artifacts resolution) have no default value for remote repositories. The local server has repo.spring.io/libs-snapshot as the default remote repository.

To pass the properties as commandline options:

```
$ java -jar <dataflow-server>.jar --maven.localRepository=mylocal
--maven.remote-repositories.repo1.url=https://repo1
--maven.remote-repositories.repo1.auth.username=repouser
--maven.remote-repositories.repo1.auth.password=repopass
--maven.remote-repositories.repo2.url=https://repo2 --maven.proxy.host=proxyhost
--maven.proxy.port=9018 --maven.proxy.auth.username=proxyuser
--maven.proxy.auth.password=proxypass
```

or, using the `SPRING_APPLICATION_JSON` environment property:

```
export SPRING_APPLICATION_JSON='{ "maven": { "local-repository": "local", "remote-repositories":
{ "repo1": { "url": "https://repo1", "auth": { "username": "repouser", "password": "repopass" } },
"repo2": { "url": "https://repo2" } }, "proxy": { "host": "proxyhost", "port":
9018, "auth": { "username": "proxyuser", "password": "proxypass" } } }'}
```

Formatted JSON:

```
SPRING_APPLICATION_JSON='{
  "maven": {
    "local-repository": "local",
    "remote-repositories": {
      "repo1": {
        "url": "https://repo1",
        "auth": {
          "username": "repouser",
          "password": "repopass"
        }
      },
      "repo2": {
        "url": "https://repo2"
      }
    },
    "proxy": {
      "host": "proxyhost",
      "port": 9018,
      "auth": {
        "username": "proxyuser",
        "password": "proxypass"
      }
    }
  }
}'
```

Note

Depending on Spring Cloud Data Flow server implementation, you may have to pass the environment properties using the platform specific environment-setting

capabilities. For instance, in Cloud Foundry, you'd be passing them as `cf set-env SPRING_APPLICATION_JSON`.

51. Logging

Spring Cloud Data Flow is built upon several Spring projects, but ultimately the dataflow-server is a Spring Boot app, so the logging techniques that apply to any [Spring Boot](#) application are applicable here as well.

While troubleshooting, following are the two primary areas where enabling the DEBUG logs could be useful.

51.1 Deployment Logs

Spring Cloud Data Flow builds upon [Spring Cloud Deployer](#) SPI and the platform specific dataflow-server uses the respective [SPI implementations](#). Specifically, if we were to troubleshoot deployment specific issues; such as the network errors, it'd be useful to enable the DEBUG logs at the underlying deployer and the libraries used by it.

1. For instance, if you'd like to enable DEBUG logs for the [local-deployer](#), you'd be starting the server with following.

```
$ java -jar <dataflow-server>.jar --logging.level.org.springframework.cloud.deployer.spi.local=DEBUG
```

(where, `org.springframework.cloud.deployer.spi.local` is the global package for everything local-deployer related)

2. For instance, if you'd like to enable DEBUG logs for the [cloudfoundry-deployer](#), you'd be setting the following environment variable and upon restaging the dataflow-server, we will see more logs around request, response and the elaborate stack traces (*upon failures*). The cloudfoundry-deployer uses [cf-java-client](#), so we will have to enable DEBUG logs for this library.

```
$ cf set-env dataflow-server JAVA_OPTS '-Dlogging.level.cloudfoundry-client=DEBUG'
$ cf restage dataflow-server
```

(where, `cloudfoundry-client` is the global package for everything cf-java-client related)

3. If there's a need to review Reactor logs, which is used by the cf-java-client, then the following would be helpful.

```
$ cf set-env dataflow-server JAVA_OPTS '-Dlogging.level.cloudfoundry-client=DEBUG -Dlogging.level.reactor.ipc.netty=DEBUG'
$ cf restage dataflow-server
```

(where, `reactor.ipc.netty` is the global package for everything reactor-netty related)

Note

Similar to the local-deployer and cloudfoundry-deployer options as discussed above, there are equivalent settings available for Apache YARN, Apache Mesos and Kubernetes variants, too. Check out the respective [SPI implementations](#) to find out more details about the packages to configure for logging.

51.2 Application Logs

The streaming applications in Spring Cloud Data Flow are Spring Boot applications and they can be independently setup with logging configurations.

For instance, if you'd have to troubleshoot the header and payload specifics that are being passed around source, processor and sink channels, you'd be deploying the stream with the following options.

```
dataflow:>stream create foo --definition "http --logging.level.org.springframework.integration=DEBUG  
/ transform --logging.level.org.springframework.integration=DEBUG / log --  
logging.level.org.springframework.integration=DEBUG" --deploy
```

(where, *org.springframework.integration* is the global package for everything Spring Integration related, which is responsible for messaging channels)

These properties can also be specified via deployment properties when deploying the stream.

```
dataflow:>stream deploy foo --properties "app.*.logging.level.org.springframework.integration=DEBUG"
```

52. Frequently asked questions

In this section, we will review the frequently discussed questions in Spring Cloud Data Flow.

52.1 Advanced SpEL expressions

One of the powerful features of SpEL expressions is [functions](#). Spring Integration provides `jsonPath()` and `xpath()` out-of-the-box [SpEL-functions](#), if appropriate libraries are in the classpath. All the provided Spring Cloud Stream application starters are supplied with the `json-path` and `spring-integration-xml` jars, thus we can use those SpEL-functions in Spring Cloud Data Flow streams whenever expressions are possible. For example we can transform JSON-aware payload from the HTTP request using some `jsonPath()` expression:

```
dataflow:>stream create jsonPathTransform --definition "http | transform --
expression=#jsonPath(payload,'$.price') | log" --deploy
...
dataflow:> http post --target http://localhost:8080 --data {"symbol":"SCDF","price":72.04}
dataflow:> http post --target http://localhost:8080 --data {"symbol":"SCDF","price":72.06}
dataflow:> http post --target http://localhost:8080 --data {"symbol":"SCDF","price":72.08}
```

In this sample we apply `jsonPath` for the incoming payload to extract just only the `price` field value. Similar syntax can be used with `splitter` or `filter` expression options. Actually any available SpEL-based option has access to the built-in SpEL-functions. For example we can extract some value from JSON data to calculate the `partitionKey` before sending output to the Binder:

```
dataflow:>stream deploy foo --
properties "deployer.transform.count=2,app.transform.producer.partitionKeyExpression=#jsonPath(payload,'$.symbol')"
```

The same syntax can be applied for `xpath()` SpEL-function when you deal with XML data. Any other custom SpEL-function can also be used, but for this purpose you should build a library with the `@Configuration` class containing an appropriate `SpelFunctionFactoryBean` `@Bean` definition. The target Spring Cloud Stream application starter should be re-packaged to supply such a custom extension via built-in Spring Boot `@ComponentScan` mechanism or auto-configuration hook.

52.2 How to use JDBC-sink?

The JDBC-sink can be used to insert message payload data into a relational database table. By default, it inserts the entire payload into a table named after the `jdbc.table-name` property, and if it is not set, by default the application expects to use a table with the name `messages`. To alter this behavior, the JDBC sink accepts [several options](#) that you can pass using the `--foo=bar` notation in the stream, or change globally. The JDBC sink has a `jdbc.initialize` property that if set to `true` will result in the sink creating a table based on the specified configuration when the it starts up. If that initialize property is `false`, which is the default, you will have to make sure that the table to use is already available.

A stream definition using `jdbc` sink relying on all defaults with MySQL as the backing database looks like the following. In this example, the system time is persisted in MySQL for every second.

```
dataflow:>stream create --name mydata --definition "time | jdbc --spring.datasource.url=jdbc:mysql://
localhost:3306/test --spring.datasource.username=root --spring.datasource.password=root --
spring.datasource.driver-class-name=org.mariadb.jdbc.Driver" --deploy
```

For this to work, you'd have to have the following table in the MySQL database.

```
CREATE TABLE test.messages
(
```

```
payload varchar(255)
);
```

```
mysql> desc test.messages;
+-----+-----+-----+-----+-----+-----+
| Field | Type          | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| payload | varchar(255) | YES  |     | NULL    |       |
+-----+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

```
mysql> select * from test.messages;
+-----+-----+
| payload |
+-----+-----+
| 04/25/17 09:10:04 |
| 04/25/17 09:10:06 |
| 04/25/17 09:10:07 |
| 04/25/17 09:10:08 |
| 04/25/17 09:10:09 |
| ..... |
| ..... |
| ..... |
+-----+-----+
```

52.3 How to use multiple message-binders?

For situations where the data is consumed and processed between two different message brokers, Spring Cloud Data Flow provides easy to override global configurations, out-of-the-box [bridge-processor](#), and DSL primitives to build these type of topologies.

Let's assume we have data queueing up in RabbitMQ (e.g., *queue = fooRabbit*) and the requirement is to consume all the payloads and publish them to Apache Kafka (e.g., *topic = barKafka*), as the destination for downstream processing.

Follow the global application of [configurations](#) to define multiple binder configurations.

```
# Apache Kafka Global Configurations (i.e., identified by "kafka1")
spring.cloud.dataflow.applicationProperties.stream.spring.cloud.stream.binders.kafka1.type=kafka
spring.cloud.dataflow.applicationProperties.stream.spring.cloud.stream.binders.kafka1.environment.spring.cloud.stream.kafka
spring.cloud.dataflow.applicationProperties.stream.spring.cloud.stream.binders.kafka1.environment.spring.cloud.stream.kafka

# RabbitMQ Global Configurations (i.e., identified by "rabbit1")
spring.cloud.dataflow.applicationProperties.stream.spring.cloud.stream.binders.rabbit1.type=rabbit
spring.cloud.dataflow.applicationProperties.stream.spring.cloud.stream.binders.rabbit1.environment.spring.rabbitmq.host=localhost
spring.cloud.dataflow.applicationProperties.stream.spring.cloud.stream.binders.rabbit1.environment.spring.rabbitmq.port=5672
```

Note

In this example, both the message brokers are running locally and reachable at `localhost` with respective ports.

These properties can be supplied in a ".properties" file that is accessible to the server directly or via `config-server`.

```
java -jar spring-cloud-dataflow-server-local/target/spring-cloud-dataflow-server-local-1.1.4.RELEASE.jar
--spring.config.location=<PATH-TO-FILE>/foo.properties
```

Spring Cloud Data Flow internally uses `bridge-processor` to directly connect different named channel destinations. Since we are publishing and subscribing from two different messaging systems, you'd have to build the `bridge-processor` with both RabbitMQ and Apache Kafka binders in the classpath. To do that, head over to start-scs.cfapps.io/ and select Bridge Processor, Kafka binder

starter, and `Rabbit binder starter` as the dependencies and follow the patching procedure described in the [reference guide](#). Specifically, for the `bridge-processor`, you'd have to import the `BridgeProcessorConfiguration` provided by the starter.

Once you have the necessary adjustments, you can build the application. Let's register the name of the application as `multiBinderBridge`.

```
dataflow:>app register --type processor --name multiBinderBridge --uri file:///<PATH-TO-FILE>/
multipleBinderBridge-0.0.1-SNAPSHOT.jar
```

It is time to create a stream definition with the newly registered processor application.

```
dataflow:>stream create fooRabbitToBarKafka --definition ":fooRabbit > multiBinderBridge --
spring.cloud.stream.bindings.input.binder=rabbit1 --spring.cloud.stream.bindings.output.binder=kafka1
> :barKafka" --deploy
```

Note

Since we are to consume messages from RabbitMQ (*i.e., identified by `rabbit1`*) and then publish the payload to Apache Kafka (*i.e., identified by `kafka1`*), we are supplying them as input and output channel settings respectively.

Note

The queue `fooRabbit` in RabbitMQ is where the stream is consuming events from and the topic `barKafka` in Apache Kafka is where the data is finally landing.

Part IX. Appendices

Appendix A. Migrating from Spring XD to Spring Cloud Data Flow

A.1 Terminology Changes

Old	New
XD-Admin	Server (<i>implementations</i> : local, cloud foundry, apache yarn, kubernetes, and apache mesos)
XD-Container	N/A
Modules	Applications
Admin UI	Dashboard
Message Bus	Binders
Batch / Job	Task

A.2 Modules to Applications

If you have custom Spring XD modules, you'd have to refactor them to use Spring Cloud Stream and Spring Cloud Task annotations, with updated dependencies and built as normal Spring Boot "applications".

Custom Applications

- Spring XD's stream and batch modules are refactored into [Spring Cloud Stream](#) and [Spring Cloud Task](#) application-starters, respectively. These applications can be used as the reference while refactoring Spring XD modules
- There are also some samples for [Spring Cloud Stream](#) and [Spring Cloud Task](#) applications for reference
- If you'd like to create a brand new custom application, use the getting started guide for [Spring Cloud Stream](#) and [Spring Cloud Task](#) applications and as well as review the development [guide](#)
- Alternatively, if you'd like to patch any of the out-of-the-box stream applications, you can follow the procedure [here](#)

Application Registration

- Custom Stream/Task application requires being installed to a maven repository for Local, YARN, and CF implementations or as docker images, when deploying to Kubernetes and Mesos. Other than maven and docker resolution, you can also resolve application artifacts from `http`, `file`, or as `hdfs` coordinates
- Unlike Spring XD, you do not have to upload the application bits while registering custom applications anymore; instead, you're expected to [register](#) the application coordinates that are hosted in the maven repository or by other means as discussed in the previous bullet

- By default, none of the out-of-the-box applications are preloaded already. It is intentionally designed to provide the flexibility to register app(s), as you find appropriate for the given use-case requirement
- Depending on the binder choice, you can manually add the appropriate binder dependency to build applications specific to that binder-type. Alternatively, you can follow the Spring Initializr [procedure](#) to create an application with binder embedded in it

Application Properties

- counter-sink:
 - The peripheral `redis` is not required in Spring Cloud Data Flow. If you intend to use the `counter-sink`, then `redis` becomes required, and you're expected to have your own running `redis` cluster
- field-value-counter-sink:
 - The peripheral `redis` is not required in Spring Cloud Data Flow. If you intend to use the `field-value-counter-sink`, then `redis` becomes required, and you're expected to have your own running `redis` cluster
- aggregate-counter-sink:
 - The peripheral `redis` is not required in Spring Cloud Data Flow. If you intend to use the `aggregate-counter-sink`, then `redis` becomes required, and you're expected to have your own running `redis` cluster

A.3 Message Bus to Binders

Terminology wise, in Spring Cloud Data Flow, the message bus implementation is commonly referred to as binders.

Message Bus

Similar to Spring XD, there's an abstraction available to extend the binder interface. By default, we take the opinionated view of [Apache Kafka](#) and [RabbitMQ](#) as the production-ready binders and are available as GA releases.

Binders

Selecting a binder is as simple as providing the right binder dependency in the classpath. If you're to choose Kafka as the binder, you'd register stream applications that are pre-built with Kafka binder in it. If you were to create a custom application with Kafka binder, you'd add the following dependency in the classpath.

```
<dependency>
  <groupId>org.springframework.cloud</groupId>
  <artifactId>spring-cloud-stream-binder-kafka</artifactId>
  <version>1.0.2.RELEASE</version>
</dependency>
```

- Spring Cloud Stream supports [Apache Kafka](#), [RabbitMQ](#) and experimental [Google PubSub](#) and [Solace JMS](#). All binder implementations are maintained and managed in their individual repositories
- Every Stream/Task application can be built with a binder implementation of your choice. All the out-of-the-box applications are pre-built for both Kafka and Rabbit and they're readily available for use as

maven artifacts [[Spring Cloud Stream](#) / [Spring Cloud Task](#) or docker images [[Spring Cloud Stream](#) / [Spring Cloud Task](#) Changing the binder requires selecting the right binder [dependency](#). Alternatively, you can download the pre-built application from this version of [Spring Initializr](#) with the desired “binder-starter” dependency

Named Channels

Fundamentally, all the messaging channels are backed by pub/sub semantics. Unlike Spring XD, the messaging channels are backed only by `topics` or `topic-exchange` and there's no representation of `queues` in the new architecture.

- `${xd.module.index}` is not supported anymore; instead, you can directly interact with named destinations
- `stream.index` changes to `:<stream-name>.<label/app-name>`
 - *for instance:* `ticktock.0` changes to `:ticktock.time`
- “topic/queue” prefixes are not required to interact with named-channels
 - *for instance:* `topic:foo` changes to `:foo`
 - *for instance:* `stream create stream1 --definition ":foo > log"`

Directed Graphs

If you're building non-linear streams, you could take advantage of named destinations to build directed graphs.

for instance, in Spring XD:

```
stream create f --definition "queue:foo > transform --expression=payload+'-foo' | log" --deploy
stream create b --definition "queue:bar > transform --expression=payload+'-bar' | log" --deploy
stream create r --definition "http | router --expression=payload.contains('a')?'queue:foo':'queue:bar'"
--deploy
```

for instance, in Spring Cloud Data Flow:

```
stream create f --definition ":foo > transform --expression=payload+'-foo' | log" --deploy
stream create b --definition ":bar > transform --expression=payload+'-bar' | log" --deploy
stream create r --definition "http | router --expression=payload.contains('a')?'foo':'bar'" --deploy
```

A.4 Batch to Tasks

A Task by definition, is any application that does not run forever, including Spring Batch jobs, and they end/stop at some point. Task applications can be majorly used for on-demand use-cases such as database migration, machine learning, scheduled operations etc. Using [Spring Cloud Task](#), users can build Spring Batch jobs as microservice applications.

- Spring Batch [jobs](#) from Spring XD are being refactored to Spring Boot applications a.k.a Spring Cloud Task [applications](#)
- Unlike Spring XD, these “Tasks” don't require explicit deployment; instead, a task is ready to be launched directly once the definition is declared

A.5 Shell/DSL Commands

Old Command	New Command
module upload	app register / app import
module list	app list
module info	app info
admin config server	dataflow config server
job create	task create
job launch	task launch
job list	task list
job status	task status
job display	task display
job destroy	task destroy
job execution list	task execution list
runtime modules	runtime apps

A.6 REST-API

Old API	New API
/modules	/apps
/runtime/modules	/runtime/apps
/runtime/modules/{moduleId}	/runtime/apps/{appId}
/jobs/definitions	/task/definitions
/jobs/deployments	/task/deployments

A.7 UI / Flo

The Admin-UI is now renamed as Dashboard. The URI for accessing the Dashboard is changed from localhost:9393/admin-ui to localhost:9393/dashboard

- (New) Apps: Lists all the registered applications that are available for use. This view includes informational details such as the URI and the properties supported by each application. You can also register/unregister applications from this view
- Runtime: Container changes to Runtime. The notion of `xd-container` is gone, replaced by out-of-the-box applications running as autonomous Spring Boot applications. The Runtime tab displays the applications running in the runtime platforms (*implementations*: cloud foundry, apache yarn, apache mesos, or kubernetes). You can click on each application to review relevant details about the application such as where it is running with, and what resources etc.

- [Spring Flo](#) is now an OSS product. Flo for Spring Cloud Data Flow's "Create Stream", the designer-tab comes pre-built in the Dashboard
- (New) Tasks:
 - The sub-tab "Modules" is renamed to "Apps"
 - The sub-tab "Definitions" lists all the Task definitions, including Spring Batch jobs that are orchestrated as Tasks
 - The sub-tab "Executions" lists all the Task execution details similar to Spring XD's Job executions

A.8 Architecture Components

Spring Cloud Data Flow comes with a significantly simplified architecture. In fact, when compared with Spring XD, there are less peripherals that are necessary to operationalize Spring Cloud Data Flow.

ZooKeeper

ZooKeeper is not used in the new architecture.

RDBMS

Spring Cloud Data Flow uses an RDBMS instead of Redis for stream/task definitions, application registration, and for job repositories. The default configuration uses an embedded H2 instance, but Oracle, DB2, SqlServer, MySQL/MariaDB, PostgreSQL, H2, and HSQLDB databases are supported. To use Oracle, DB2 and SqlServer you will need to create your own Data Flow Server using [Spring Initializr](#) and add the appropriate JDBC driver dependency.

Redis

Running a Redis cluster is only required for analytics functionality. Specifically, when the `counter-sink`, `field-value-counter-sink`, or `aggregate-counter-sink` applications are used, it is expected to also have a running instance of Redis cluster.

Cluster Topology

Spring XD's `xd-admin` and `xd-container` server components are replaced by stream and task applications themselves running as autonomous Spring Boot applications. The applications run natively on various platforms including Cloud Foundry, Apache YARN, Apache Mesos, or Kubernetes. You can develop, test, deploy, scale +/-, and interact with (Spring Boot) applications individually, and they can evolve in isolation.

A.9 Central Configuration

To support centralized and consistent management of an application's configuration properties, [Spring Cloud Config](#) client libraries have been included into the Spring Cloud Data Flow server as well as the Spring Cloud Stream applications provided by the Spring Cloud Stream App Starters. You can also [pass common application properties](#) to all streams when the Data Flow Server starts.

A.10 Distribution

Spring Cloud Data Flow is a Spring Boot application. Depending on the platform of your choice, you can download the respective release uber-jar and deploy/push it to the runtime platform (cloud foundry,

apache yarn, kubernetes, or apache mesos). For example, if you're running Spring Cloud Data Flow on Cloud Foundry, you'd download the Cloud Foundry server implementation and do a `cf push` as explained in the [reference guide](#).

A.11 Hadoop Distribution Compatibility

The `hdfs-sink` application builds upon Spring Hadoop 2.4.0 release, so this application is compatible with following Hadoop distributions.

- Cloudera - cdh5
- Pivotal Hadoop - phd30
- Hortonworks Hadoop - hdp24
- Hortonworks Hadoop - hdp23
- Vanilla Hadoop - hadoop26
- Vanilla Hadoop - 2.7.x (default)

A.12 YARN Deployment

Spring Cloud Data Flow can be deployed and used with Apache YARN in two different ways.

- Deploy the server [directly](#) in a YARN cluster
- Leverage Apache Ambari [plugin to provision](#) Spring Cloud Data Flow as a service

A.13 Use Case Comparison

Let's review some use-cases to compare and contrast the differences between Spring XD and Spring Cloud Data Flow.

Use Case #1

(It is assumed both XD and SCDF distributions are already downloaded)

Description: Simple `ticktock` example using local/singlenode.

Spring XD	Spring Cloud Data Flow
Start <code>xd-singlenode</code> server from CLI <pre># xd-singlenode</pre>	Start a binder of your choice Start <code>local-server</code> implementation of SCDF from the CLI <pre># java -jar spring-cloud-dataflow-server-local-1.0.0.BUILD-SNAPSHOT.jar</pre>
Start <code>xd-shell</code> server from the CLI <pre># xd-shell</pre>	Start <code>dataflow-shell</code> server from the CLI

Spring XD	Spring Cloud Data Flow
	<pre># java -jar spring-cloud-dataflow-shell-1.0.0.BUILD-SNAPSHOT.jar</pre>
Create ticktock stream <code>xd:>stream create ticktock --definition "time log" --deploy</code>	Create ticktock stream <code>dataflow:>stream create ticktock --definition "time log" --deploy</code>
Review ticktock results in the xd-singlenode server console	Review ticktock results by tailing the ticktock.log/stdout_log application logs

Use Case #2

(It is assumed both XD and SCDF distributions are already downloaded)

Description: Stream with custom module/application.

Spring XD	Spring Cloud Data Flow
Start xd-singlenode server from CLI <pre># xd-singlenode</pre>	Start a binder of your choice Start local-server implementation of SCDF from the CLI <pre># java -jar spring-cloud-dataflow-server-local-1.0.0.BUILD-SNAPSHOT.jar</pre>
Start xd-shell server from the CLI <pre># xd-shell</pre>	Start dataflow-shell server from the CLI <pre># java -jar spring-cloud-dataflow-shell-1.0.0.BUILD-SNAPSHOT.jar</pre>
Register custom "processor" module to transform payload to a desired format <code>xd:>module upload --name toupper --type processor --file <CUSTOM_JAR_FILE_LOCATION></code>	Register custom "processor" application to transform payload to a desired format <code>dataflow:>app register --name toupper --type processor --uri <MAVEN_URI_COORDINATES></code>
Create a stream with custom module <code>xd:>stream create testupper --definition "http toupper log" --deploy</code>	Create a stream with custom application <code>dataflow:>stream create testupper --definition "http toupper log" --deploy</code>
Review results in the xd-singlenode server console	Review results by tailing the testupper.log/stdout_log application logs

Use Case #3

(It is assumed both XD and SCDF distributions are already downloaded)

Description: Simple batch-job.

Spring XD	Spring Cloud Data Flow
Start xd-singlenode server from CLI <pre># xd-singlenode</pre>	Start local-server implementation of SCDF from the CLI <pre># java -jar spring-cloud-dataflow-server-local-1.0.0.BUILD-SNAPSHOT.jar</pre>
Start xd-shell server from the CLI <pre># xd-shell</pre>	Start dataflow-shell server from the CLI <pre># java -jar spring-cloud-dataflow-shell-1.0.0.BUILD-SNAPSHOT.jar</pre>
Register custom “batch-job” module <pre>xd:>module upload --name simple-batch --type job --file <CUSTOM_JAR_FILE_LOCATION></pre>	Register custom “batch-job” as task application <pre>dataflow:>app register --name simple-batch --type task --uri <MAVEN_URI_COORDINATES></pre>
Create a job with custom batch-job module <pre>xd:>job create batchtest --definition "simple-batch"</pre>	Create a task with custom batch-job application <pre>dataflow:>task create batchtest --definition "simple-batch"</pre>
Deploy job <pre>xd:>job deploy batchtest</pre>	NA
Launch job <pre>xd:>job launch batchtest</pre>	Launch task <pre>dataflow:>task launch batchtest</pre>
Review results in the xd-singlenode server console as well as Jobs tab in UI (executions sub-tab should include all step details)	Review results by tailing the batchtest/ stdout_log application logs as well as Task tab in UI (executions sub-tab should include all step details)

Appendix B. Building

To build the source you will need to install JDK 1.8.

The build uses the Maven wrapper so you don't have to install a specific version of Maven. To enable the tests for Redis you should run the server before building. See below for more information on how to run Redis.

The main build command is

```
$ ./mvnw clean install
```

You can also add '-DskipTests' if you like, to avoid running the tests.

Note

You can also install Maven ($\geq 3.3.3$) yourself and run the `mvn` command in place of `./mvnw` in the examples below. If you do that you also might need to add `-P spring` if your local Maven settings do not contain repository declarations for spring pre-release artifacts.

Note

Be aware that you might need to increase the amount of memory available to Maven by setting a `MAVEN_OPTS` environment variable with a value like `-Xmx512m -XX:MaxPermSize=128m`. We try to cover this in the `.mvn` configuration, so if you find you have to do it to make a build succeed, please raise a ticket to get the settings added to source control.

The projects that require middleware generally include a `docker-compose.yml`, so consider using [Docker Compose](#) to run the middleware servers in Docker containers. See the README in the [scripts demo repository](#) for specific instructions about the common cases of mongo, rabbit and redis.

B.1 Documentation

There is a "full" profile that will generate documentation. You can build just the documentation by executing

```
$ ./mvnw clean package -DskipTests -P full -pl spring-cloud-dataflow-server-yarn-docs -am
```

B.2 Working with the code

If you don't have an IDE preference we would recommend that you use [Spring Tools Suite](#) or [Eclipse](#) when working with the code. We use the [m2eclipse](#) eclipse plugin for maven support. Other IDEs and tools should also work without issue.

Importing into eclipse with m2eclipse

We recommend the [m2eclipse](#) eclipse plugin when working with eclipse. If you don't already have m2eclipse installed it is available from the "eclipse marketplace".

Unfortunately m2e does not yet support Maven 3.3, so once the projects are imported into Eclipse you will also need to tell m2eclipse to use the `.settings.xml` file for the projects. If you do not do this

you may see many different errors related to the POMs in the projects. Open your Eclipse preferences, expand the Maven preferences, and select User Settings. In the User Settings field click Browse and navigate to the Spring Cloud project you imported selecting the `.settings.xml` file in that project. Click Apply and then OK to save the preference changes.

**Note**

Alternatively you can copy the repository settings from [.settings.xml](#) into your own `~/ .m2/ settings.xml`.

Importing into eclipse without m2eclipse

If you prefer not to use m2eclipse you can generate eclipse project metadata using the following command:

```
$ ./mvnw eclipse:eclipse
```

The generated eclipse projects can be imported by selecting `import existing projects` from the `file` menu.

Appendix C. Contributing

Spring Cloud is released under the non-restrictive Apache 2.0 license, and follows a very standard Github development process, using Github tracker for issues and merging pull requests into master. If you want to contribute even something trivial please do not hesitate, but follow the guidelines below.

C.1 Sign the Contributor License Agreement

Before we accept a non-trivial patch or pull request we will need you to sign the [contributor's agreement](#). Signing the contributor's agreement does not grant anyone commit rights to the main repository, but it does mean that we can accept your contributions, and you will get an author credit if we do. Active contributors might be asked to join the core team, and given the ability to merge pull requests.

C.2 Code Conventions and Housekeeping

None of these is essential for a pull request, but they will all help. They can also be added after the original pull request but before a merge.

- Use the Spring Framework code format conventions. If you use Eclipse you can import formatter settings using the `eclipse-code-formatter.xml` file from the [Spring Cloud Build](#) project. If using IntelliJ, you can use the [Eclipse Code Formatter Plugin](#) to import the same file.
- Make sure all new `.java` files to have a simple Javadoc class comment with at least an `@author` tag identifying you, and preferably at least a paragraph on what the class is for.
- Add the ASF license header comment to all new `.java` files (copy from existing files in the project)
- Add yourself as an `@author` to the `.java` files that you modify substantially (more than cosmetic changes).
- Add some Javadocs and, if you change the namespace, some XSD doc elements.
- A few unit tests would help a lot as well — someone has to do it.
- If no-one else is using your branch, please rebase it against the current master (or other target branch in the main project).
- When writing a commit message please follow [these conventions](#), if you are fixing an existing issue please add `Fixes gh-XXXX` at the end of the commit message (where XXXX is the issue number).
