This guide describes how to use Spring Session to transparently leverage a relational to back a web application's `HttpSession` with XML based configuration.

NOTE You can find the completed guide in the [httpSession-jdbc-xml sample application](#).

[Index](#)

Updating Dependencies

Before you use Spring Session, you must update your dependencies. If you are using Maven, you must add the following dependencies:

pom.xml

```
<dependencies>
    <!-- ... -->

    <dependency>
        <groupId>org.springframework.session</groupId>
        <artifactId>spring-session-jdbc</artifactId>
        <version>2.3.0.RELEASE</version>
        <type>pom</type>
    </dependency>
    <dependency>
        <groupId>org.springframework</groupId>
        <artifactId>spring-web</artifactId>
        <version>5.2.6.RELEASE</version>
    </dependency>
</dependencies>
```

Spring XML Configuration

After adding the required dependencies, we can create our Spring configuration. The Spring configuration is responsible for creating a servlet filter that replaces the `HttpSession` implementation with an implementation backed by Spring Session. The following listing shows how to add the following Spring Configuration:

src/main/webapp/WEB-INF/spring/session.xml

```
① <context:annotation-config/>
<bean
  class="org.springframework.session.jdbc.config.annotation.web.http.JdbcHttpSession
Configuration"/>

② <jdbc:embedded-database id="dataSource" database-name="testdb" type="H2">
  <jdbc:script location="classpath:org/springframework/session/jdbc/schema-
h2.sql"/>
</jdbc:embedded-database>

③ <bean class="org.springframework.jdbc.datasource.DataSourceTransactionManager">
  <constructor-arg ref="dataSource"/>
</bean>
```

- ① We use the combination of `<context:annotation-config/>` and `JdbcHttpSessionConfiguration` because Spring Session does not yet provide XML Namespace support (see [gh-104](#)). This creates a Spring bean with the name of `springSessionRepositoryFilter`. That bean implements `Filter`. The filter is in charge of replacing the `HttpSession` implementation to be backed by Spring Session. In this instance, Spring Session is backed by a relational database.
- ② We create a `dataSource` that connects Spring Session to an embedded instance of an H2 database. We configure the H2 database to create database tables by using the SQL script that is included in Spring Session.
- ③ We create a `transactionManager` that manages transactions for previously configured `dataSource`.

For additional information on how to configure data access-related concerns, see the [Spring Framework Reference Documentation](#).

XML Servlet Container Initialization

Our [Spring Configuration](#) created a Spring bean named `springSessionRepositoryFilter` that implements `Filter`. The `springSessionRepositoryFilter` bean is responsible for replacing the `HttpSession` with a custom implementation that is backed by Spring Session.

In order for our `Filter` to do its magic, we need to instruct Spring to load our `session.xml` configuration. We do so with the following configuration:

```
src/main/webapp/WEB-INF/web.xml
```

```
<context-param>
    <param-name>contextConfigLocation</param-name>
    <param-value>
        /WEB-INF/spring/session.xml
    </param-value>
</context-param>
<listener>
    <listener-class>
        org.springframework.web.context.ContextLoaderListener
    </listener-class>
</listener>
```

The `ContextLoaderListener` reads the `contextConfigLocation` and picks up our `session.xml` configuration.

Last, we need to ensure that our Servlet Container (that is, Tomcat) uses our `springSessionRepositoryFilter` for every request. The following snippet performs this last step for us:

```
src/main/webapp/WEB-INF/web.xml
```

```
<filter>
    <filter-name>springSessionRepositoryFilter</filter-name>
    <filter-class>org.springframework.web.filter.DelegatingFilterProxy</filter-
class>
</filter>
<filter-mapping>
    <filter-name>springSessionRepositoryFilter</filter-name>
    <url-pattern>/*</url-pattern>
    <dispatcher>REQUEST</dispatcher>
    <dispatcher>ERROR</dispatcher>
</filter-mapping>
```

The `DelegatingFilterProxy` looks up a bean named `springSessionRepositoryFilter` and casts it to a `Filter`. For every request on which `DelegatingFilterProxy` is invoked, the

`springSessionRepositoryFilter` is invoked.

httpsession-jdbc-xml Sample Application

This section describes how to work with the httpsession-jdbc-xml Sample Application.

Running the httpsession-jdbc-xml Sample Application

You can run the sample by obtaining the [source code](#) and invoking the following command:

```
$ ./gradlew :spring-session-sample-xml-jdbc:tomcatRun
```

You should now be able to access the application at <http://localhost:8080/>

Exploring the httpsession-jdbc-xml Sample Application

Now you can try using the application. To do so, fill out the form with the following information:

- **Attribute Name:** *username*
- **Attribute Value:** *rob*

Now click the **Set Attribute** button. You should now see the values displayed in the table.

How Does It Work?

We interact with the standard `HttpSession` in the following `SessionServlet`:

```
src/main/java/sample/SessionServlet.java

public class SessionServlet extends HttpServlet {

    @Override
    protected void doPost(HttpServletRequest req, HttpServletResponse resp) throws
    IOException {
        String attributeName = req.getParameter("attributeName");
        String attributeValue = req.getParameter("attributeValue");
        req.getSession().setAttribute(attributeName, attributeValue);
        resp.sendRedirect(req.getContextPath() + "/");
    }

    private static final long serialVersionUID = 2878267318695777395L;
}
```

Instead of using Tomcat's `HttpSession`, we persist the values in the H2 database. Spring Session

creates a cookie named **SESSION** in your browser. That cookie contains the ID of your session. You can view the cookies (with [Chrome](#) or [Firefox](#)).

You can remove the session by using H2 web console available at: <http://localhost:8080/h2-console/> (use `jdbc:h2:mem:testdb` for JDBC URL)

Now you can visit the application at <http://localhost:8080/> and observe that the attribute we added is no longer displayed.
